

# **Laboratory of mathematical methods and models in bioinformatics**

Institute for Information Transmission  
Problems, Russian Academy of Sciences

lyubetsk@iitp.ru,  
<http://lab6.iitp.ru/en/>

**Directions 2-4 (thirteen tasks and  
corresponding results):**

**Regulation (itself)  
and  
evolution of cellular processes**

- 1) Transcription regulation based on **protein – DNA** interaction. Evolution =Ev.
- 2) Allied to 1: Searching for **conserved** and **highly labile** promoters. Ev.
- 3) Translation regulation of gene expression based on **RBS blocking by a secondary structure**. Ev.
- 4) Transcription regulation of gene expression based on terminator and antiterminator **secondary structures competition**. Different **regulation mechanisms** based on it. Ev.
- 5) Transcription and translation regulation with **triplexes and pseudoknots**. Ev.
- 6) On the whole **evolution of regulations** based on the **secondary structure dynamics** (original modifications made to the parsimony functional)

7) **The role of RNA sites in pathogen invasion:**

*Toxoplasma gondii* (Apicomplexa) switches on plastid genes in the host cell

8) **Transcription regulation in nucleus** in the  
Piroplasmida

9) **The role of RNA secondary structures in pathogen invasion:** *Brucella* (alpha-proteo) competes for the macrophage host cell resources (metal cations) using the RNA secondary structure

10) Secondary structures are often used in **bacteria in defense against their phages**

11) **Secondary structures in DNA (crest-hairpins)**

12-13) **RNA polymerase competition** as an important transcription-related process:

the competition drives **physiological responses** (e.g., to heat shock); and/or **regulation responses**

(physiological or tissue-specific through the interaction of nuclear and plastid genomes)

Below there are some our results about all  
13 tasks listed above

# 1) Transcription regulation based on **protein – DNA** interaction

Original results on the evolution of this regulation for genes *proA* (gamma-glutamyl phosphate reductase) and *proB* (gamma-glutamyl kinase) were already shown (the first presentation = Direction 1).

In such studies the **regulation itself is to be found first.**

Now is another example: original results on regulation of **nitrogen metabolism**

**NtcA- or NtcB-regulated genes in cyanobacteria are listed according to their product function (genes with regulation in all species are in blue):**

### **Nitrogen metabolism:**

- nitrate/nitrite: *narB*, *narK/nrtP*, *nirA*, *nirB*
- glutamate/glutamine: *glnA*, *glnN*, *glnB*, *gifA*, *gifB*, *gltS*, *hisH*, *cobA*, *cobB*
- NAD-dependent isocitrate dehydrogenase: *icd*
- arginase/agmatinase: *speB*
- urease accessory proteins: *ureE*, *ureG*.

**Heterocyst differentiation protein:** *hetC*.

**Transcription factors:** *ntcA*, *ntcB*.

**Carbon fixation:** *ccmK*, *rbcL*, *rpe*

**Transporters:** *urtA*, *urtB*, *urtC*, *urtD*, *urtE*, *amtB/amt1*, *tauA*, *tauB*, *tauC*, *nrtA*, *cmpA*, *cynA*, *cynB*, *cynD*, *cynS*, *devB*, *futC*,

**Porin:** *som*; **Pigments and photosynthesis:** *psaI*, *psaB*, *psaL*, *psaF*, *psbA3*, *psbZ*, *psbB*, *psbO*, *psbW*, *psbE*, *psb27*, *isiB*, *isiA*, *pcbD*, *pcbA*, *ndhB*, *peth*, *petF/fdx*, *apcF*, *apcE*, *apcA*, *cpcB*, *trxA*, *trxM*

**Metalloproteins:** *hypA2*, *hypB*, *moaA*, *moaC*, *moeA*

**Others:** *metG*, *thrC*, *mutS*, *rnc*, *xisA*, *gor*, *aarF*, *rpoD*

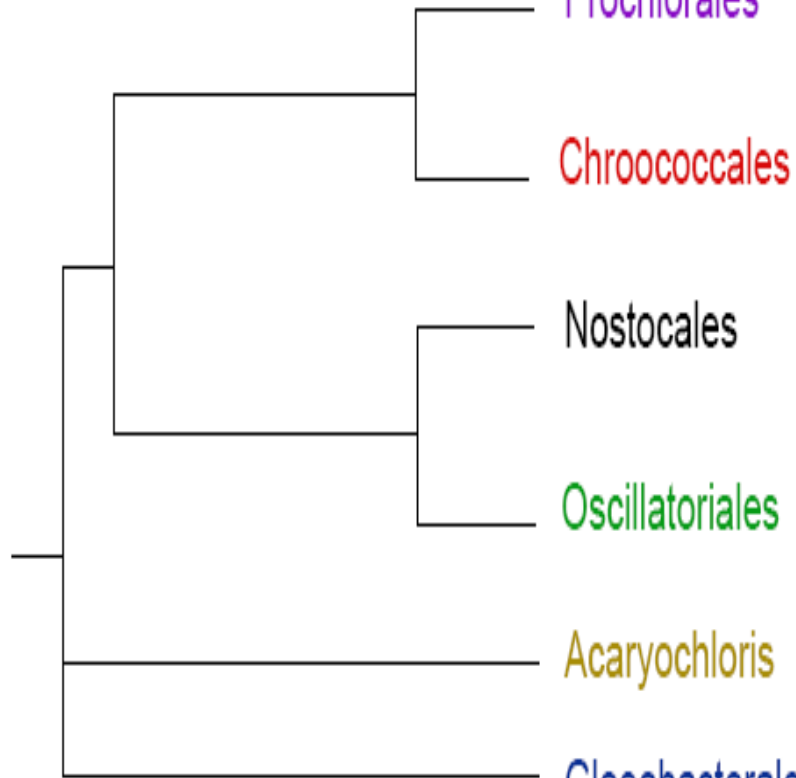

**Nucleotide frequency profile of the *NtcA* binding motifs predicted in cyanobacteria. Underlined are conserved positions in the obtained consensus:**

**Nucleotide frequency profile of the *NtcB* binding motifs:**

# High taxonomy of Cyanobacteria

Site and gene are together				“there is gene and no site”	
—	<b>+glnA</b>	—	—	<b>+icd</b>	<b>+narB</b>
<b>+glnN</b>	<b>+glnA</b>	<b>+gifA</b>	<b>+gifB</b>	<b>+icd</b>	<i>narB</i>
—	<b>+glnA</b>	<b>+gifA</b>	<b>+gifB</b>	<b>+icd</b>	<i>narB</i>
—	<b>+glnA</b>	<b>+gifA</b>	<b>+gifB</b>	<b>+icd</b>	<i>narB</i>
<b>+glnN</b>	<b>+glnA</b>	<b>+gifA</b>	<b>+gifB</b>	<i>icd</i>	<b>+narB</b>
<b>+glnN</b>	<b>+glnA</b>	—	—	<i>icd</i>	<i>narB</i>

Site and gene present: «**+gene**»; only gene present «**gene**», both absent «—»

The above results are obtained with two original programs:

1. “Twobox”: finding sites with complex structure
2. “Treealign”: tree-guided alignment

2) Technically related task is **searching for widely conserved and labile promoters.**

E.g., in plastids of plants and algae including secondary and tertiary endosymbionts

While the amino acid sequences of plastid-encoded proteins are **highly conserved**, the noncoding gene regions substantially **vary even in closely related species**, suggesting an important role in the regulation of gene expression

*psaA*

## The first result here:

**Lack of conservation** of bacterial type promoters in plastids of Streptophyta.

Namely,

**we found widely conserved PEP-promoters**

**ONLY** for plastid genes *psaA*, *psbA*, *psbB*,  
*psbE*, *rbcL*

The opposite case is  
evolutionary **labile promoters**

**What is known about lability? Little:**

there is ample published research on the promoter comparisons within small lineages, largely the studies of the promoters and their transcription factors in gamma- and alpha-proteobacteria [Collado-Vides, *J Bacteriol.* 2009].

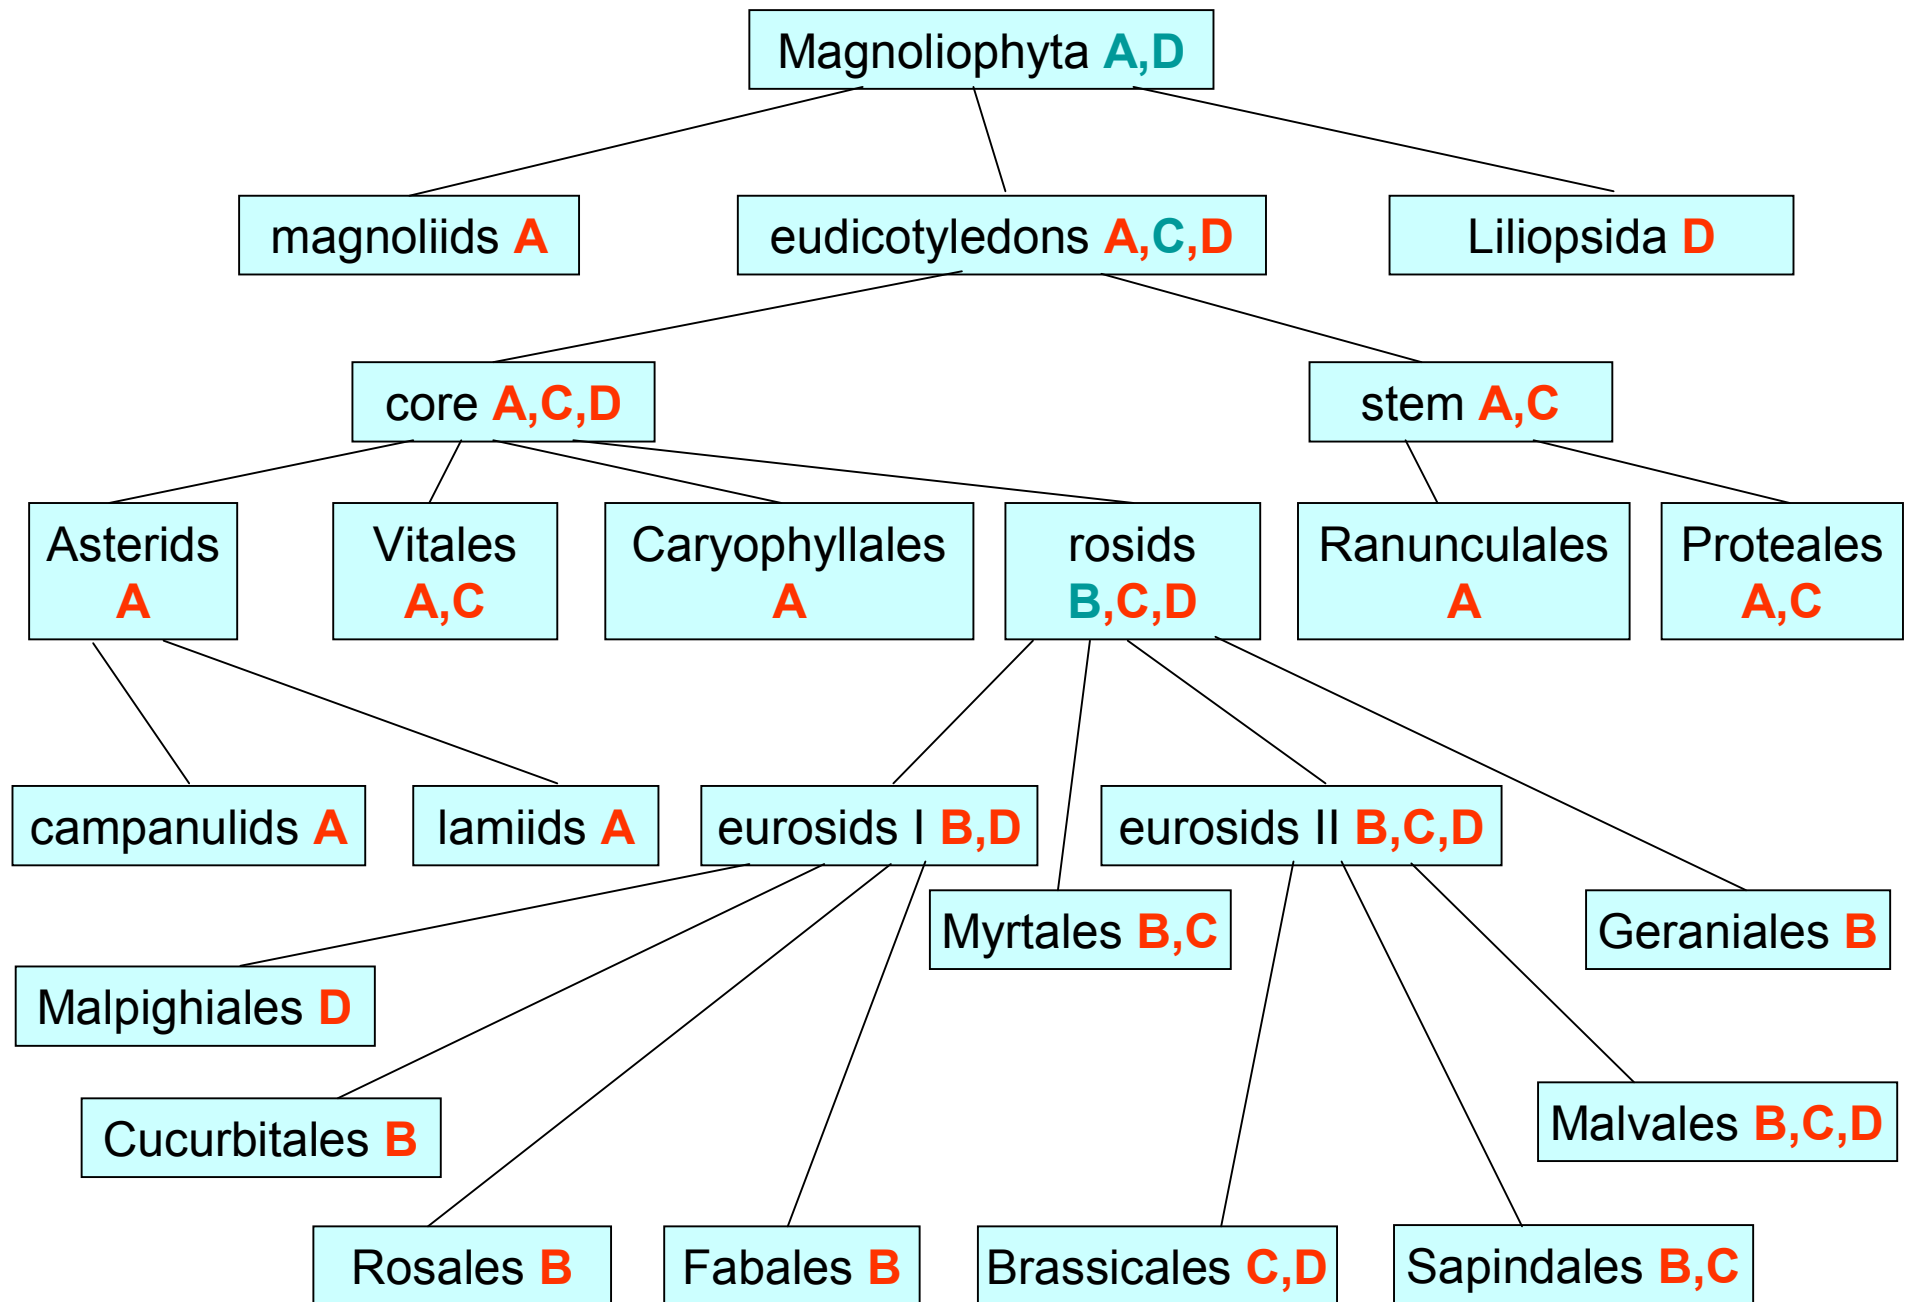

Further, some pairs of closely related species were shown to possess largely diverged promoters [Swiatecka-Hagenbruch, *Mol Genet Genomics* 2007; Hoffer, *Plant Physiol*, 1997]

We report on evolutionary **labile** PEP-promoters for some genes in **narrow lineages**, e.g. for the *ndhF* gene in **dicotyledonous angiosperm plants**.

### **The second result:**

for *ndhF* we described **four different promoter types**, which are likely to have **replaced each other during evolution**

# Suggested evolution of *ndhF* promoters in flowering plants

# C-type of the potential PEP-promoter

A **next level task**: searching for **transcription and translation regulations based on dynamics of RNA secondary structure** and **inferring their evolution**.

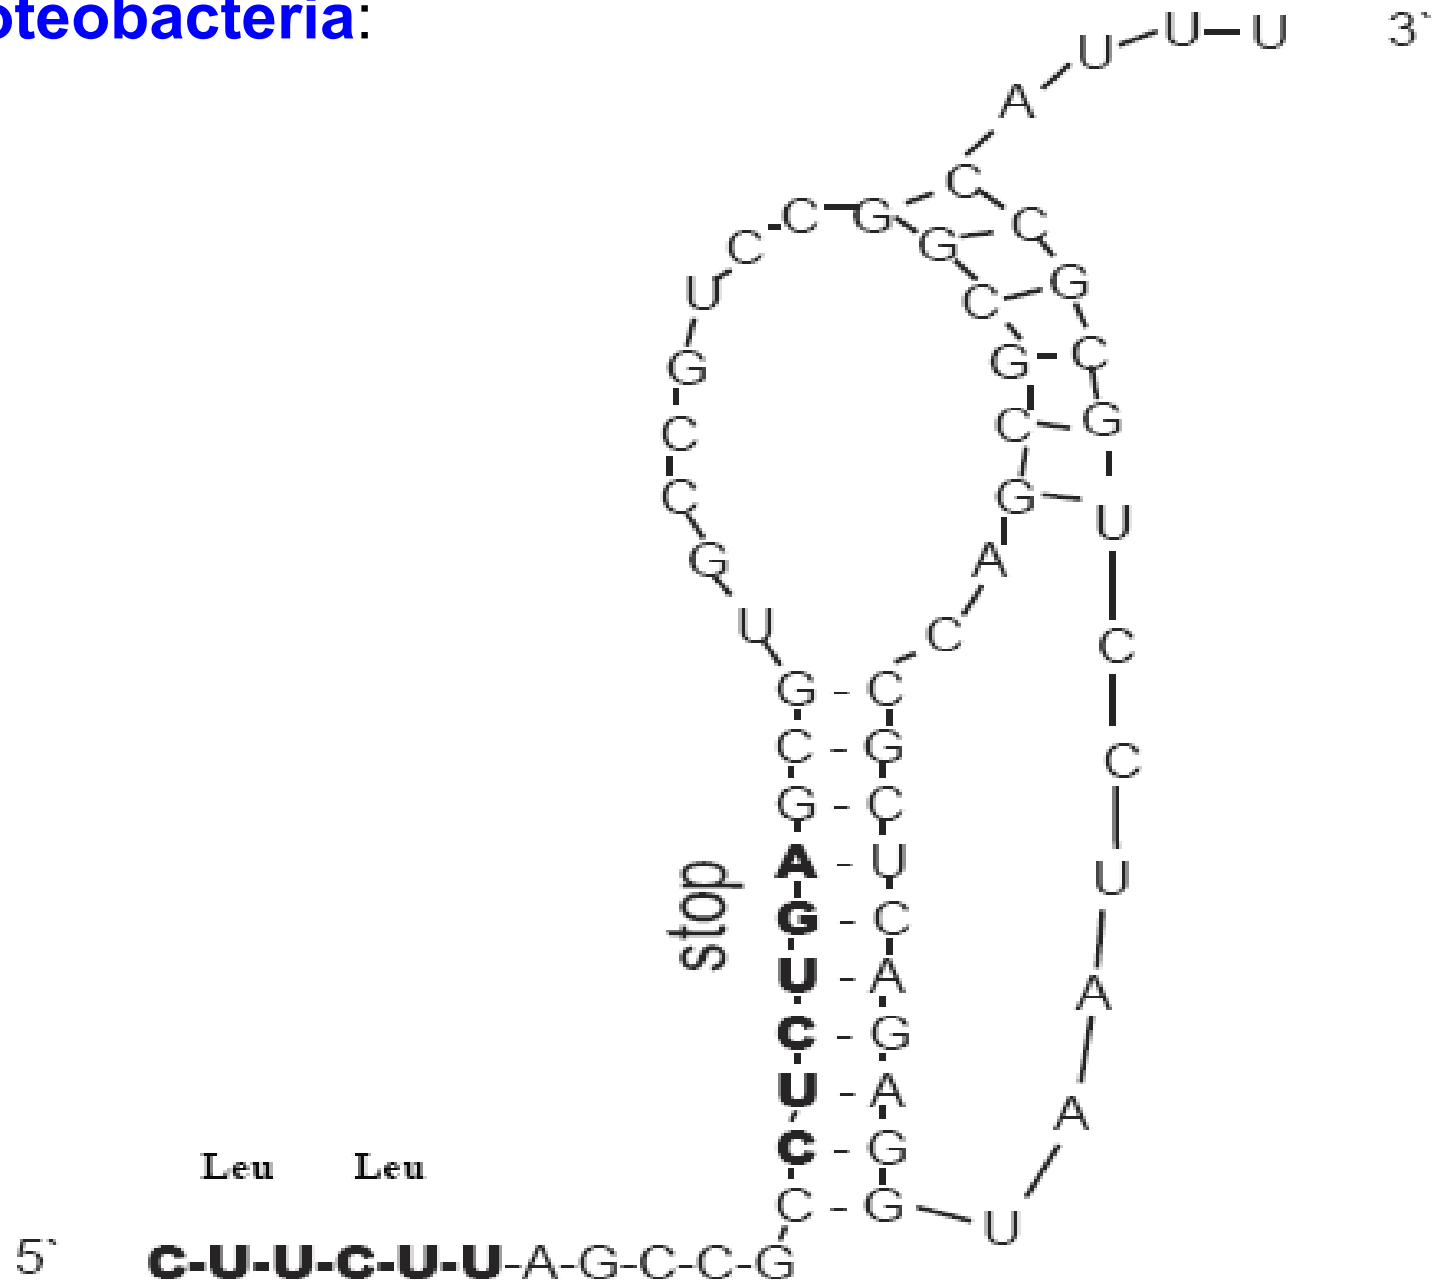

Here radically new approaches are required to both find the regulation and infer its evolution.

3) **Translation regulation** of gene expression  
through  
**blocking RBS by a secondary structure**

Translation regulation: LEU-pseudoknot in *Mycobacterium bovis*. It is conserved in **almost all Actinobacteria**

**LEU1-pseudknot** in *Dinoroseobacter shibae* and **many**  
**alphaproteobacteria:**

4) **Transcription regulation** of gene expression  
through **competition of two structures:**  
terminator and antiterminator

# Classic attenuation by Yanofsky: definitions of “antiterminator” and “terminator”

Tryptophan starvation

**Antitermination**

Tryptophan abundance

**Termination**

## Types of classic attenuation regulation:

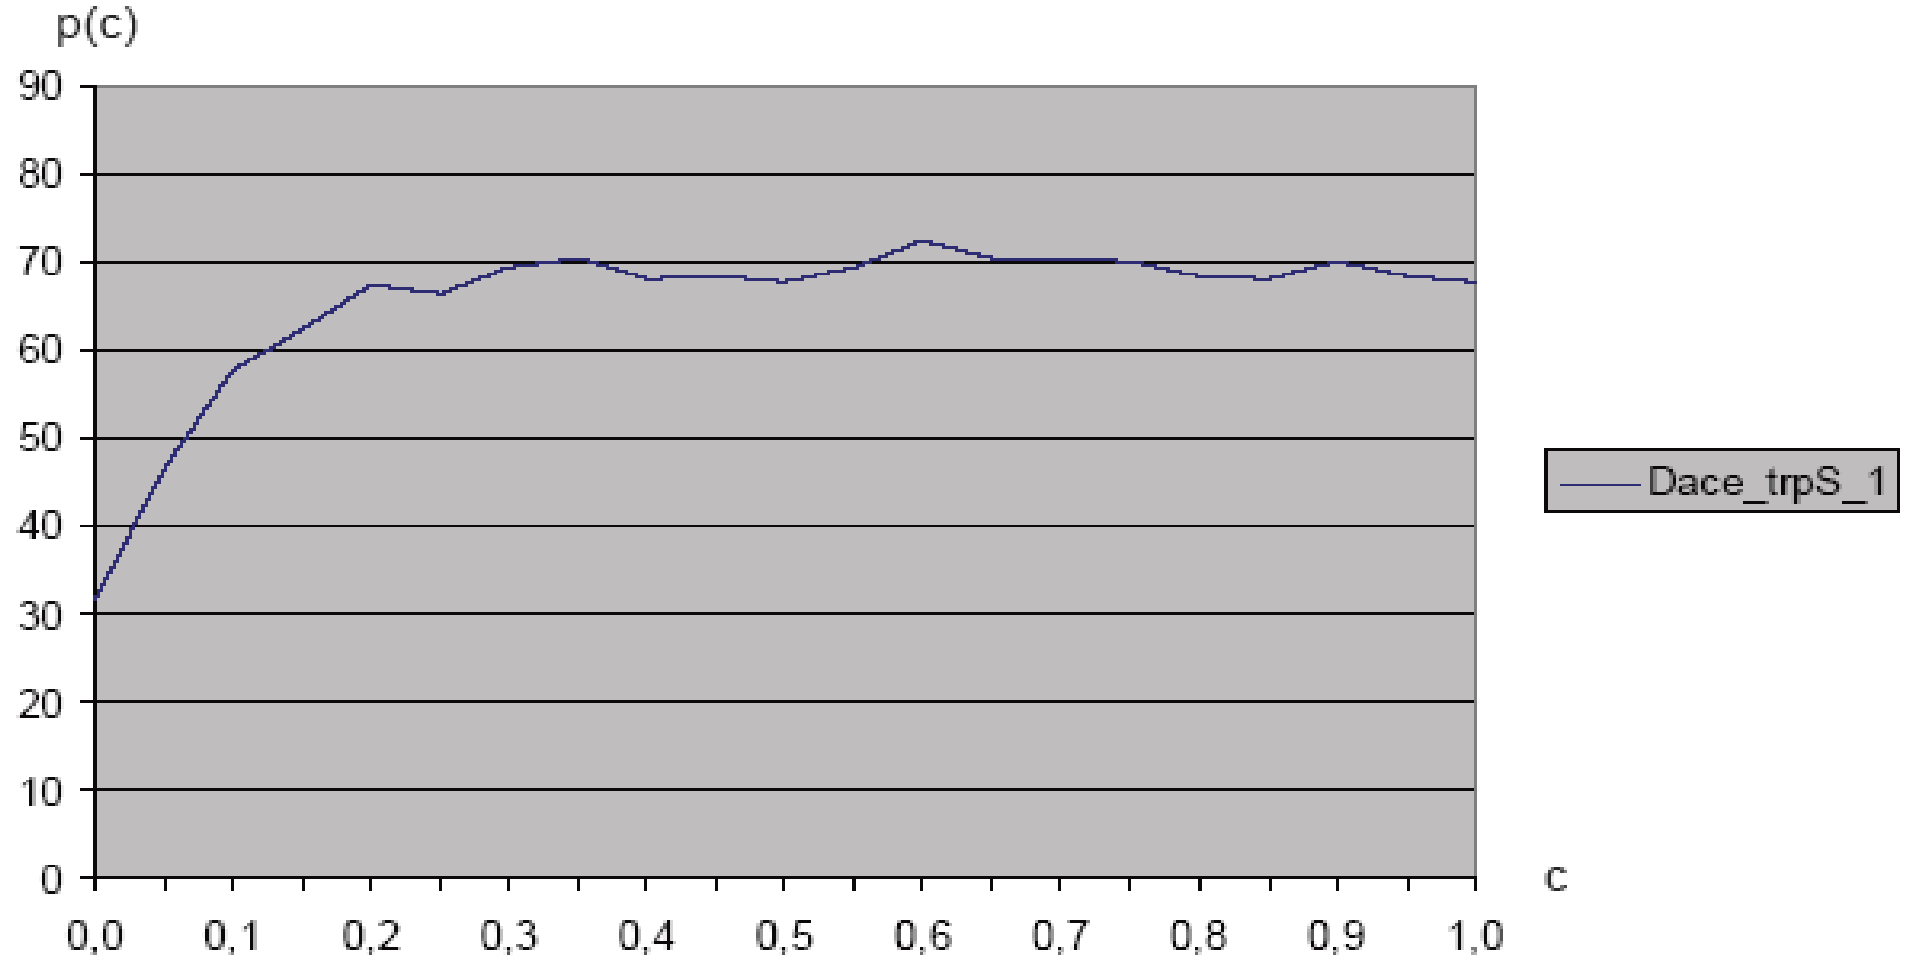

- «**by Yanofsky**»: terminator and antiterminator have mutually exclusive structure; the 3'-end of terminator has an adjacent poly-U run;
- «**succession of hairpins**»: **terminator and antiterminator are not mutually exclusive**, but there exists a succession of usually four hairpins, from which the first one is the antiterminator prohibiting the formation of the next hairpin (co-terminator) thus leading to the formation of the third hairpin (co-antiterminator) prohibiting the fourth one (terminator); 3'- poly-U run is present; in this case hairpins are usually stabilized with the formation of RNA triplexes;
- «**assembly of hairpins**»: conserved **antiterminator is replaced by a group of hairpins**, with each being exclusive to a conserved terminator; poly-U run is present, **hairpins may be stabilized by RNA triplexes**;
- «**sequester-attenuation**» regulation follows below

Occurrence of **classical attenuation regulation** in major bacterial taxa  
 (**non-classic attenuation** LEU and LEU1 in the last column)

AUGACAUUACAGCGAUGGUGGUGGGGUCAGCCUUUAUGGACUGAUCGGUGGCCUUUCGGUUUUUUGACAUCACAGACUGGGCCGGGCACGGGGGGCAACAUAUGAAAUCACACAAGCCGGGAUGAUCGUAUCGGGGCUUGUU

# Sequester-attenuation regulation in *Bordetella pertussis*

No poly-U  
and CAR,  
but RBS  
present

Here are two variants of antisequester but not many:

**5) Transcription and translation regulations**  
with **triplexes and pseudoknots**

## The role of RNA triplex

The RNA triplex is a structure formed with Hoogsteen hydrogen bonds between a region of mRNA («third shoulder») and the stem of a Pu-Py helix. The third shoulder may be located in front of the left shoulder. A triplex is formed with N--Pu-Py triads (usually U--A-U), where the Pu-Py pair comes from the helix. The third shoulder has the same orientation as the purine shoulder of the helix.

## RNA triplexes in *his* regulation

Many  $\gamma$ -proteobacteria possess a **triplex** upstream gene *hisG* **stabilizing the co-terminator**. Its third shoulder contains many poly-U runs, which make it stable regardless of the cytoplasm acidity. Usually it is formed with Py--Pu-Py triads. In *Alteromonadales bacterium* and *Pseudoalteromonas haloplanktis*, however, the triplex CUGU--GAGG-CCUC is composite (Py--Pu-Py and Pu--Pu-Py triads).

The permease-coding gene *lysQ* in *Lactococcus lactis* (Firmicutes) has CAR with **histidine regulatory codons** and a **hairpin succession where the co-terminator is stabilized** with the Pu--Pu-Py **triplex** AGA--AGA-UCU

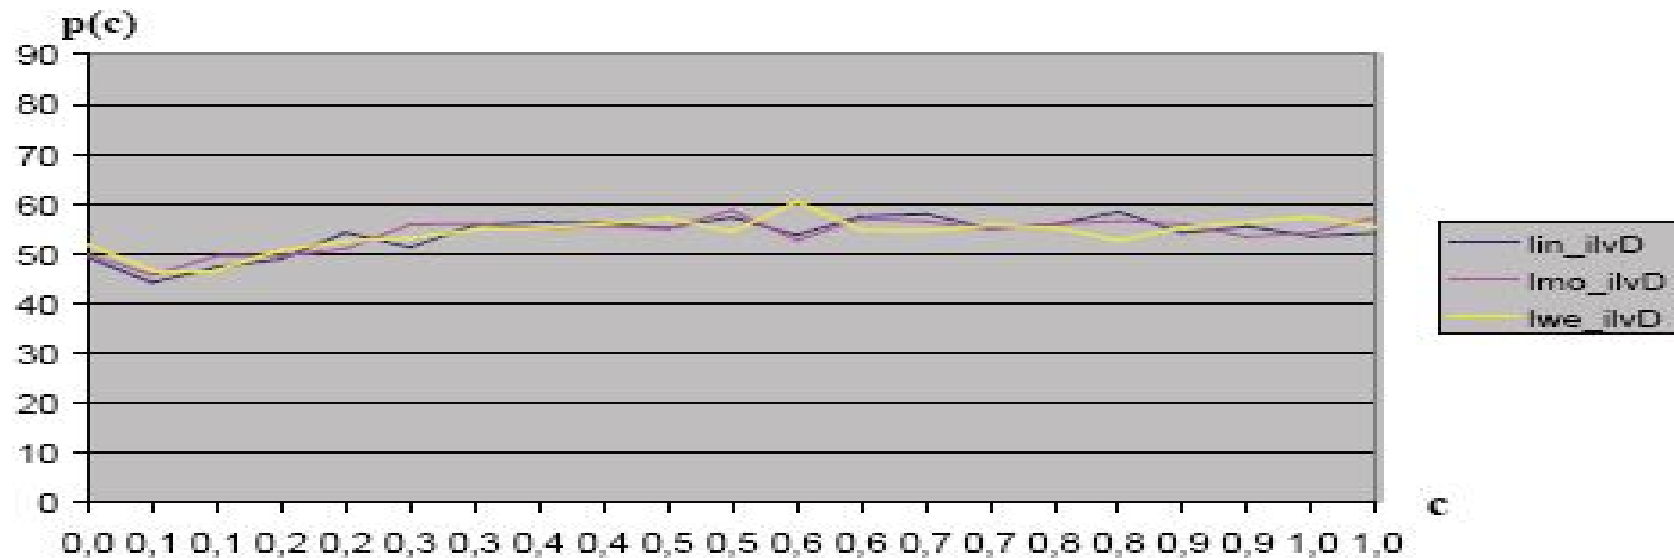

## RNA triplexes in *ilvD* regulation

Regulatory regions upstream *ilvD* in *Staphylococcus* and *Listeria* (Firmicutes) **possess a succession of four conserved hairpins** forming a Py--Pu-Py **triplex** in the co-terminator.

Modeling this and the *hisG* cases suggests the **importance of taking the energy of the co-terminator triplex** into account.

This result and the observed **conservativity of triplexes** support their importance in calculating RNA secondary structures

# Probability of the *ilvD* operon termination in *Listeria* **without** and **with** RNA triplex energies

# Antiterminator and terminator exist together under low concentration but terminator is blocked by pseudoknot

*Mycobacterium microti* (Actinobacteria, gene *ilvB*) ???

AUGCUCGUAGUAAUU GGUCGGCGGGUUGGUGCCUGACUAGCCCAAGCGAGCACCAACGCG ACCCUCGUGCAGCAGCUGAGCUGGCGAGGGUUUUUU

6) **Evolution of regulations based on the secondary structure dynamics**

7) Plastids of **Apicomplexa** resemble those of **red algae**.

- **Importance of plastids:** the **Apicomplexa** (secondary endosymbionts) are **protozoan infection agents, and many illnesses like that;**
- **All plastids** are good **targets for drugs** affecting bacterial RNA polymerases or ribosomes, thus being safe for the eukaryotic host cell

**The role of plastid RNA sites in  
pathogen invasion:**

*Toxoplasma gondii* (Apicomplexa) switches on  
plastid genes in the host cell.

Also other **regulations**

Bacterial type regulation of gene *ycf24* in **rhodophytes**, **plasmodia**, **coccidia**: a hypothetical protein factor binding site overlapping the **RBS** in mRNA:

<i>G. tenuistipitata</i>	GAAUUA AAAUACUGAUUAUUAUAAUUAU=====
<i>P. purpurea</i>	AAUAUGAAUA=UUUUAUAAAUAAUUAUUUGUUGCACU==
<i>P. yezoensis</i>	GAAUUAAGAU=UUAUAUAAAUAAUUA AAAUGUUUCAUU==
<i>Pl. berghei</i>	ACUUGAAUAUUUUUAUAAUUA AAAAUUAUU=====
<i>Pl. chabaudi</i>	ACUUACAUAUUUUUAUAAUUA AAAAUUAUU=====
<i>Pl. falciparum</i>	AGCUUUUAUUUUUUUAUUAUAAAUUAUU=====
<i>Pl. yoelii</i>	AAUUUAAAUA=UAUUCUUUAAA AUUUUUAAAU=====
<i>E. tenella</i>	AAUAAUAAAUA=UUAUAUAAAAAUUUUAAA=====
<i>T. gondii</i>	AUUUUUUUAUU=UUAUAUUAUUAAUUUUUUUUUACUAAAU

Here conserved regions in 5'-UTR adjoin the start codon of *ycf24*.

This signal is **not detected in other orthologous groups**.

This signal existing in the ancestor of these species **diversifies within one descendant**:

In *Toxoplasma gondii* this regulation extends onto genes *rps4* and *rpoB*:

nearly identical regions upstream *ycf24*, *rps4* and *rpoB*;  
**signal absent upstream other genes**;

**regulation affects all** plastome genes through the regulation of **ribosome protein S4 and  $\beta$ -subunit** of RNA polymerase;

experimentally proved: in *Toxoplasma gondii* **plastids** are **essential for virulence but not critical for *in vitro* survival**, [Wilson et al. 2003. *Phil. Trans. R. Soc. Lond.*].

**Hypothesis**: this regulation sustains the **pathogenicity of *T. gondii***

## Translation regulation (excess of subunits) of RNA polymerase $\beta$ -subunits (= *rpoB*) in plastids

*P. purpurea* AAUAUUAAA CUCUU CAAUUUCAGAAUUUGCUAUAAAGGAGAU CU=  
*P. yezoensis* AGUAUUAAA CUCUU CGAUUUCAA AAUUUGUU AUAAAGGAGAU CU=  
*E. tenella* AUAAUUAAA UUAUUUAAAAUAAUUAAU AUUAAUUAUUUUUUAUAUA

rhodophytes and coccidia; conserved sites (in blue) constitute a putative mRNA-protein binding site that overlaps the RBS (according to *RpoB* protein alignment);

signal **not detected in other orthologous groups**;

in *E. coli* similar regulation is found at the translation level [Passador *et al*, 1992, *J. Bacteriology*]: a  $\beta$ -subunit binds to a specific mRNA site and **interrupts translation**

**8) Transcription regulation in nucleus**  
in the Piroplasmida

## Alignment of the rubredoxin and kinase regulatory regions (transcription in nucleus)

Вид	Белок	Консервативный сайт
<i>B. bovis</i>	rubredoxin	ACCTCGATGCCCTACAGAT=ATAGAATCTAGGCGGCA
<i>B. bovis</i>	kinase	ACTTTCATGAACAGCAGG==ATATAAATCAAATGAAA
<i>Th. annulata</i>	rubredoxin	TCAGTAATGTTACACACCCCAATAGAATCCCAGGACA
<i>Th. annulata</i>	kinase	TCAGTCATGCCCGACATC==ATACCATCTATAAAAAA
<i>Th. parva</i>	rubredoxin	TTGGTAAAGTTACACACCCGATAGAATCCCAGGGCA
<i>Th. parva</i>	kinase	TCAGTCATGCCCGACATC==ATATAATCTATAAAACA
<i>T. pseudonana</i>	rubredoxin, ch1	TCAATCCTGCCATCCACATCATAAAGTCCTCCTCAGA
<i>T. pseudonana</i>	rubredoxin, ch14	GCAATAATTCAAAACACACAATGCGACACGTACCCCA
<i>T. pseudonana</i>	kinase, ch1	TCATTTTGCCCTCACTAAT=ATTTAATGCCAACAGAC
<i>Ph. tricornutum</i>	rubredoxin, ch30	TCACACTTGCCAATCAATCGCTTCAACCTCAAGGAGA
<i>Ph. tricornutum</i>	kinase, ch26	TCTCTCTTTCTGTGCGTCGTCTACAAGCCCGAAGGCA

Species are piroplasmids and diatoms. Kinases phosphorylate tyrosine in proteins. **The signal is not predicted in other orthologous groups.**

In *Th. parva* the region begins upstream the kinase transcription start codon at position -46. We assume: **this is a protein-DNA regulation affecting a promoter**

**Rubredoxins under regulation** contain a very similar domain:

<i>B. bovis</i>	RYQCTGCGFTIFPAKNREERFFSSSFTCPNCGAAKNKF
<i>Th. parva</i>	RYQCTSCGYVIFPARNREEKFFSESFTCPNCGSPRSKF
<i>Th. annulata</i>	RYQCTSCGYVIFPARNREEKFFSESFTCPNCGSPRSKF
<i>T. pseudonana</i> ch1	AKECQKCGYVLFIAPIRESKFFSPSFQCPQCGAPKRQF
<i>T. pseudonana</i> ch14	AYSCKTCGATIFIARHREWFFKGGNTECTNCGAPQPLA
<i>Ph. tricornutum</i> ch30	VYECGECGYTLFVAQGRESKFFGTGFKCPECGAAKKQF

These (and two paralogs) are found in nuclei of **diatom algae** and parasitic **Piroplasmida** (*Theileria*, *Babesia*).

In the conserved (blue) active center of rubredoxins four cysteine residues (green) bind a Fe ion (the ferro-sulfuric center); **it is a subfamily of rubredoxins**

# Regulation in Apicomplexa and algae (very similar plastids but not their regulations):

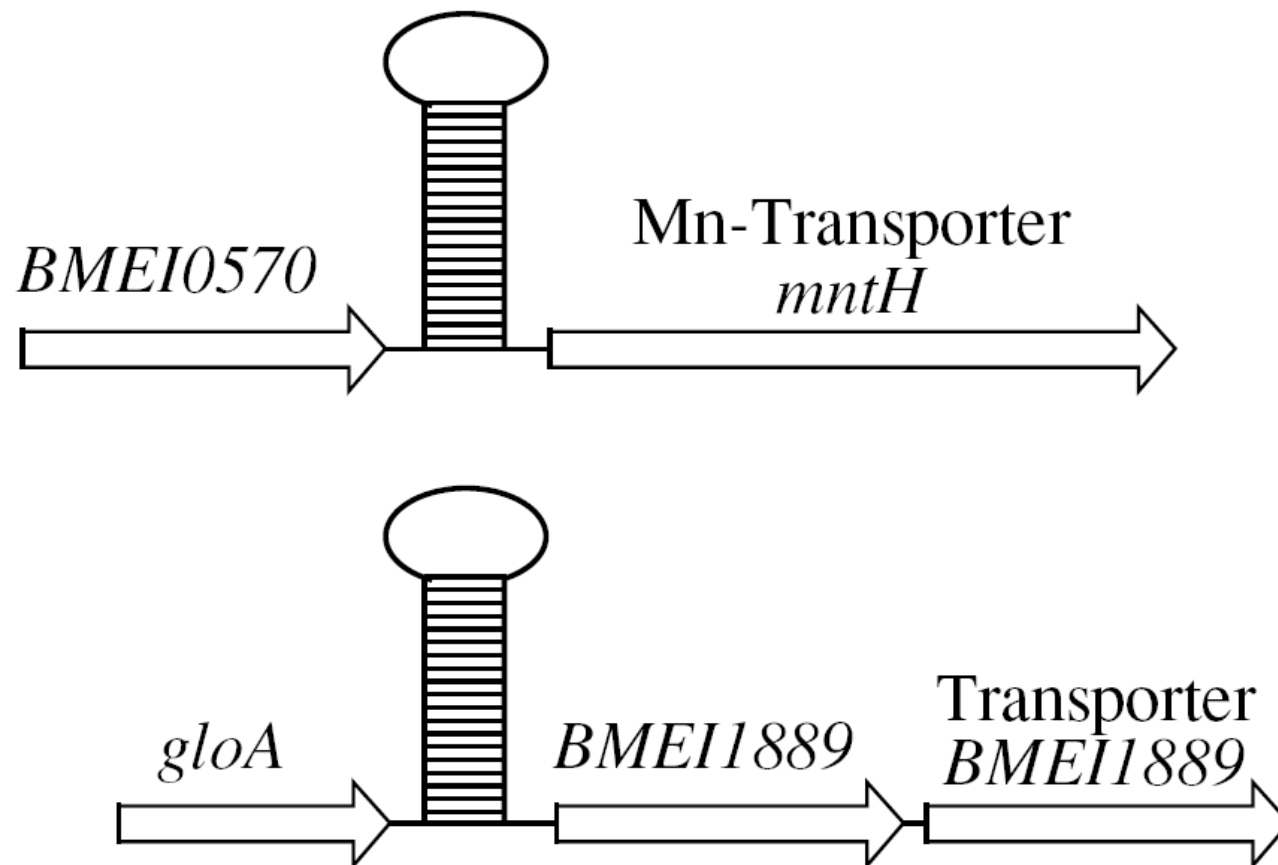

# The role of RNA secondary structures in pathogen invasion:

9) *Brucella* (alpha-proteo) competes for the host macrophage cell resources (metal cations) using RNA secondary structures

It was found that divalent cation transporters of the Nramp family in eukaryotic cell phagosomes and bacteria that parasitize these cells compete for metals that are vital for bacterial survival. Long helices were determined in the 5'-untranslated region for each mRNA in *Brucella*.

Long helices of quite similar nucleotide composition were found in mRNAs that encode manganese transporters and Ni-dependent glyoxalase I. **We suggest** that long helices in these regions are involved in the regulation of RNA stability

The helices were found between close (up to 300 nt apart) genes on the same strand that are not separated by a usual terminator. Therefore, the genes might belong to the same operon

# *Brucella helices*

10) Secondary structures are often used in bacteria in defense against their phages

## **11) Secondary DNA structures (crest-hairpins)**

T1 and T2 from BD-10.

These hairpins are common also in actinobacteria  
in the trailer regions of highly transcribed genes

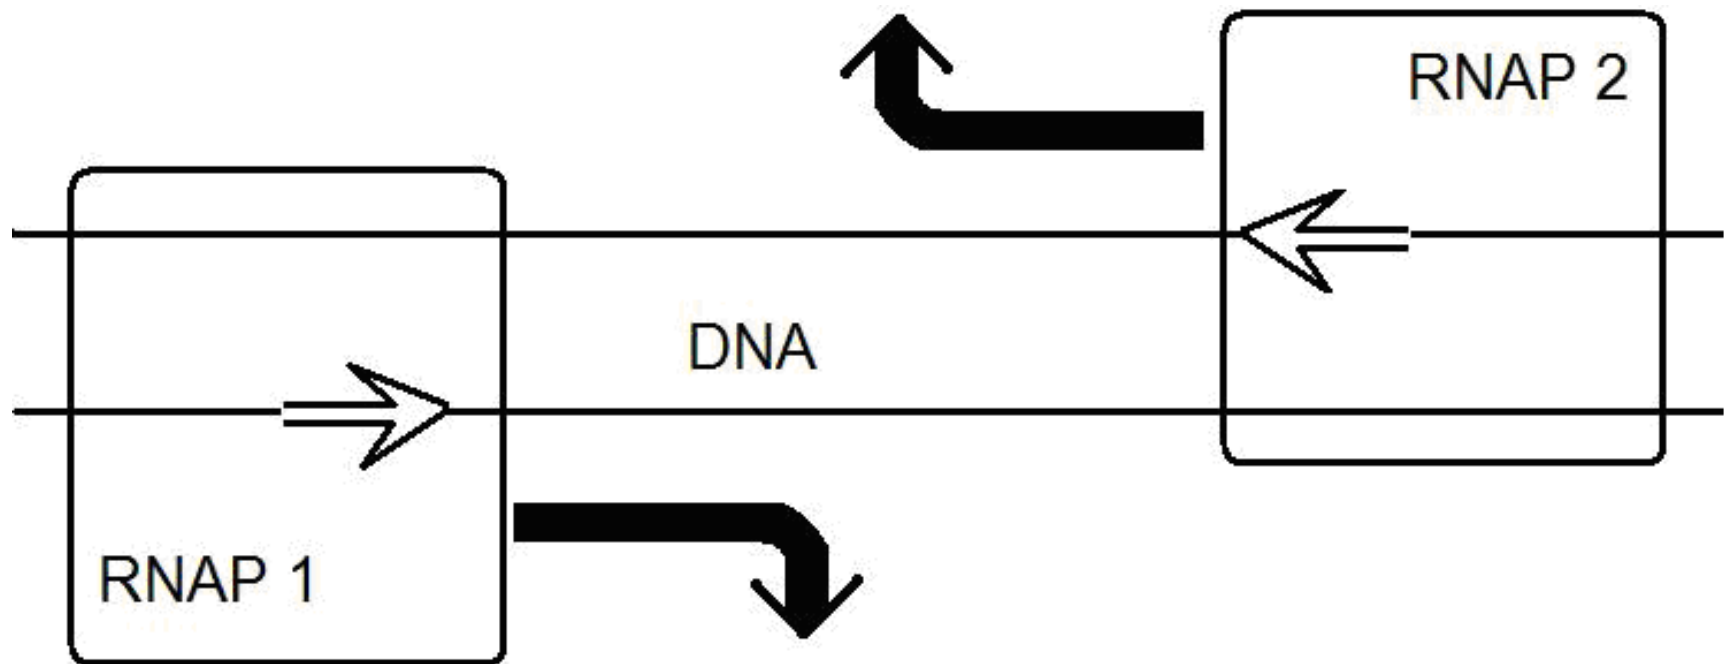

## 12-13) RNA polymerase competition as an important transcription-related process:

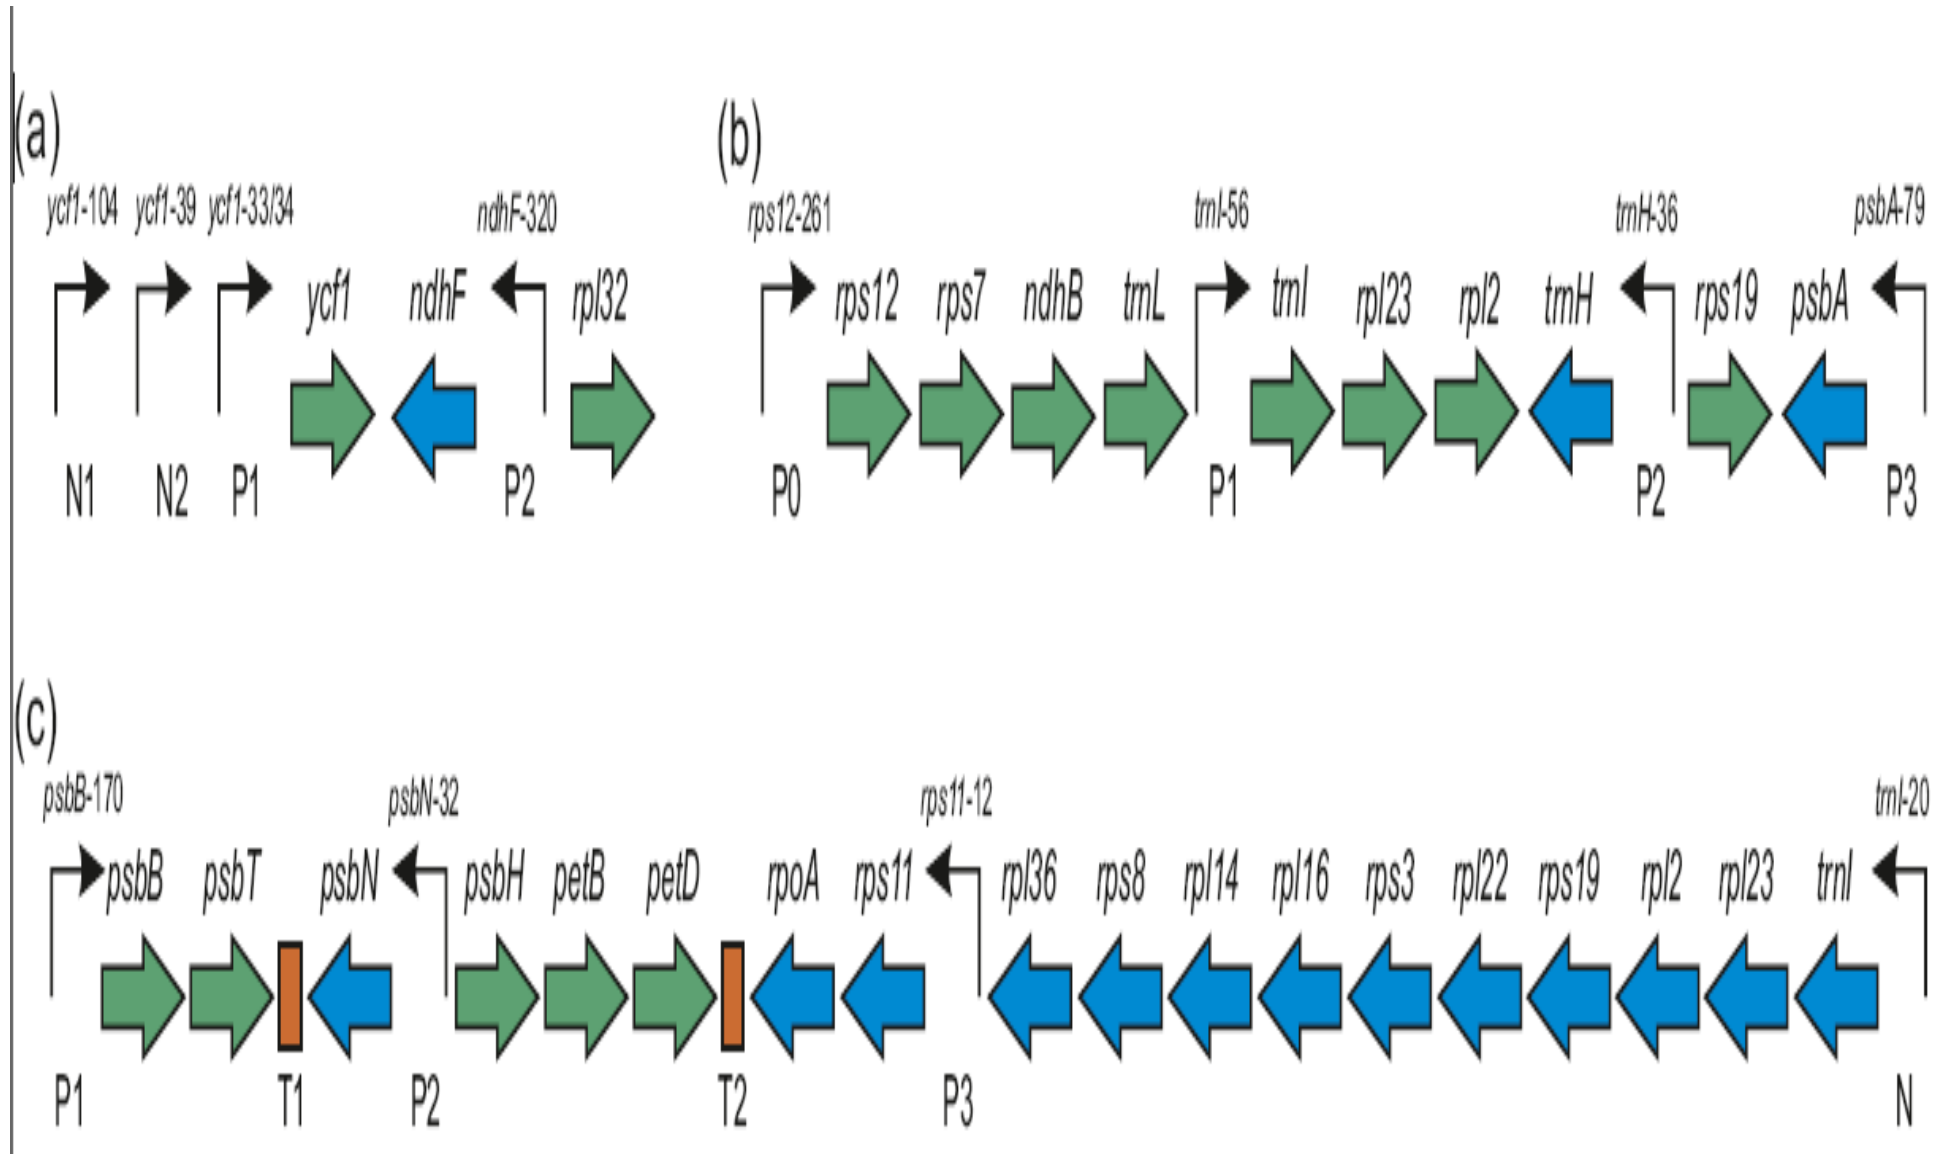

the competition drives **physiological responses** (e.g., to heat shock);

and regulation **responses** (physiological or tissue-specific through the interaction of nuclear and plastid genomes)

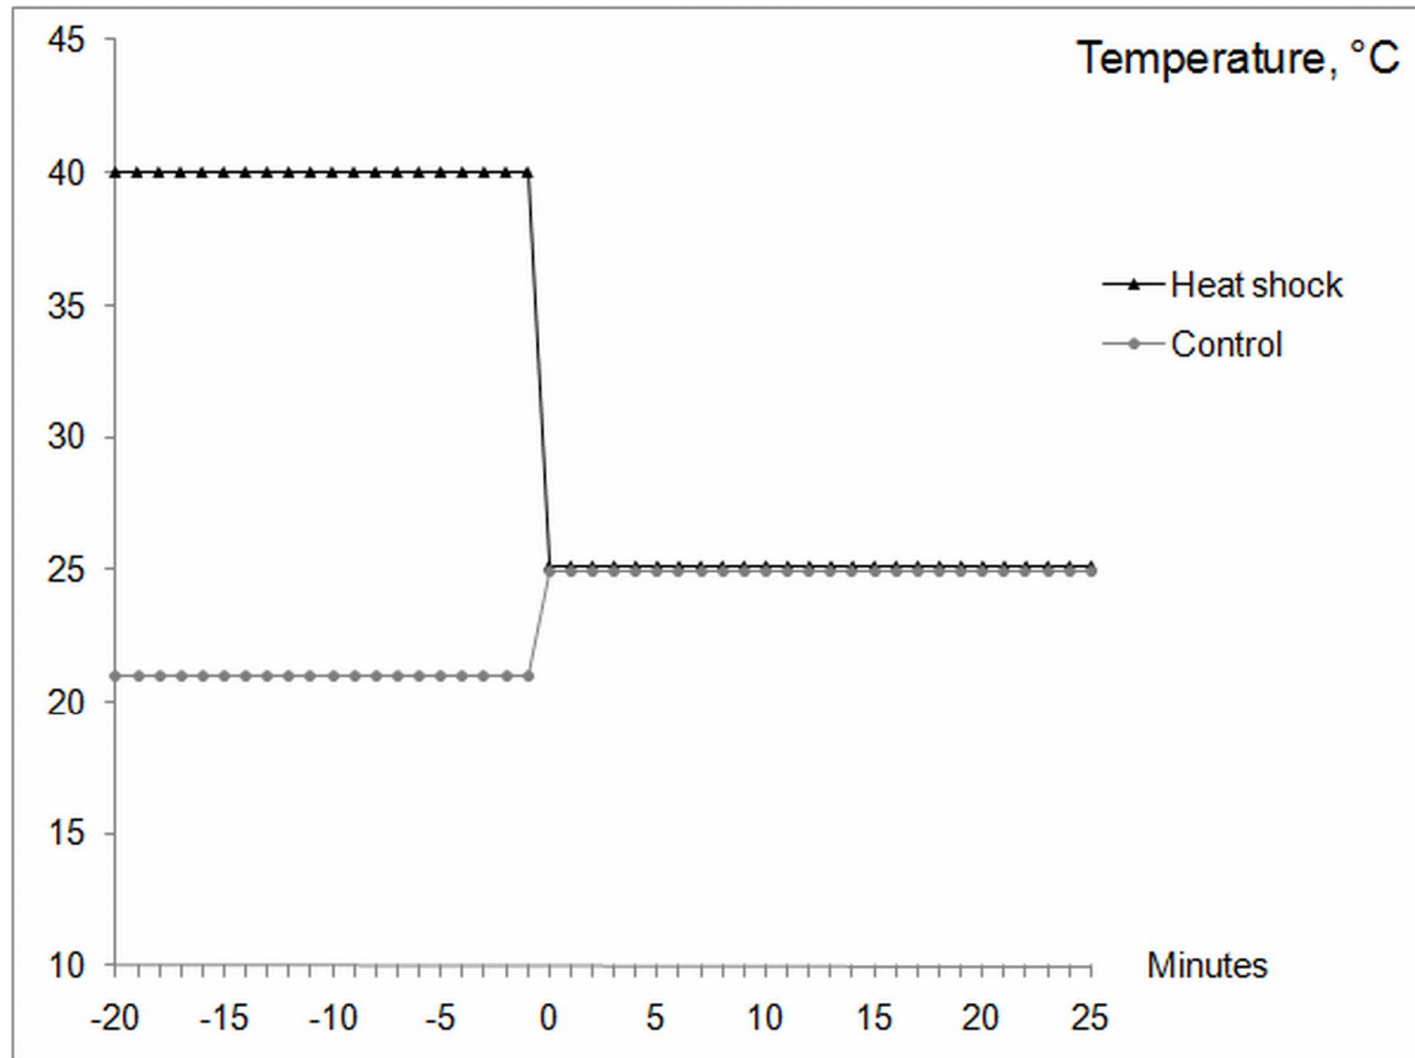

Competition:  
RNA polymerases on complementary DNA strands collide  
and detach

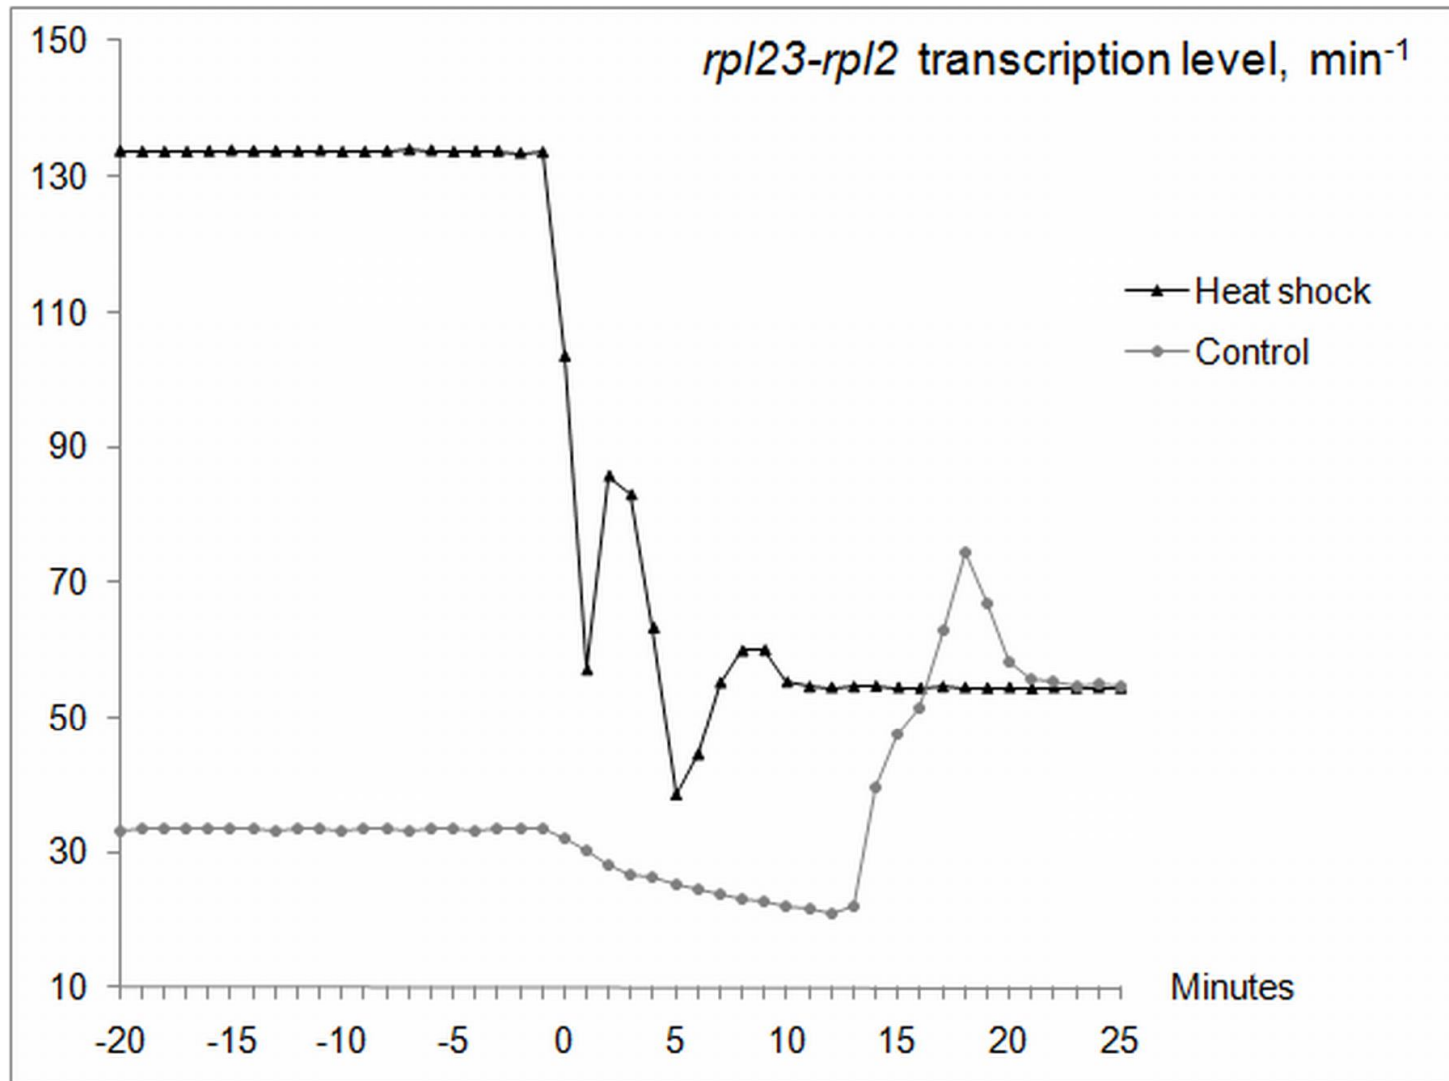

# Examples of loci:

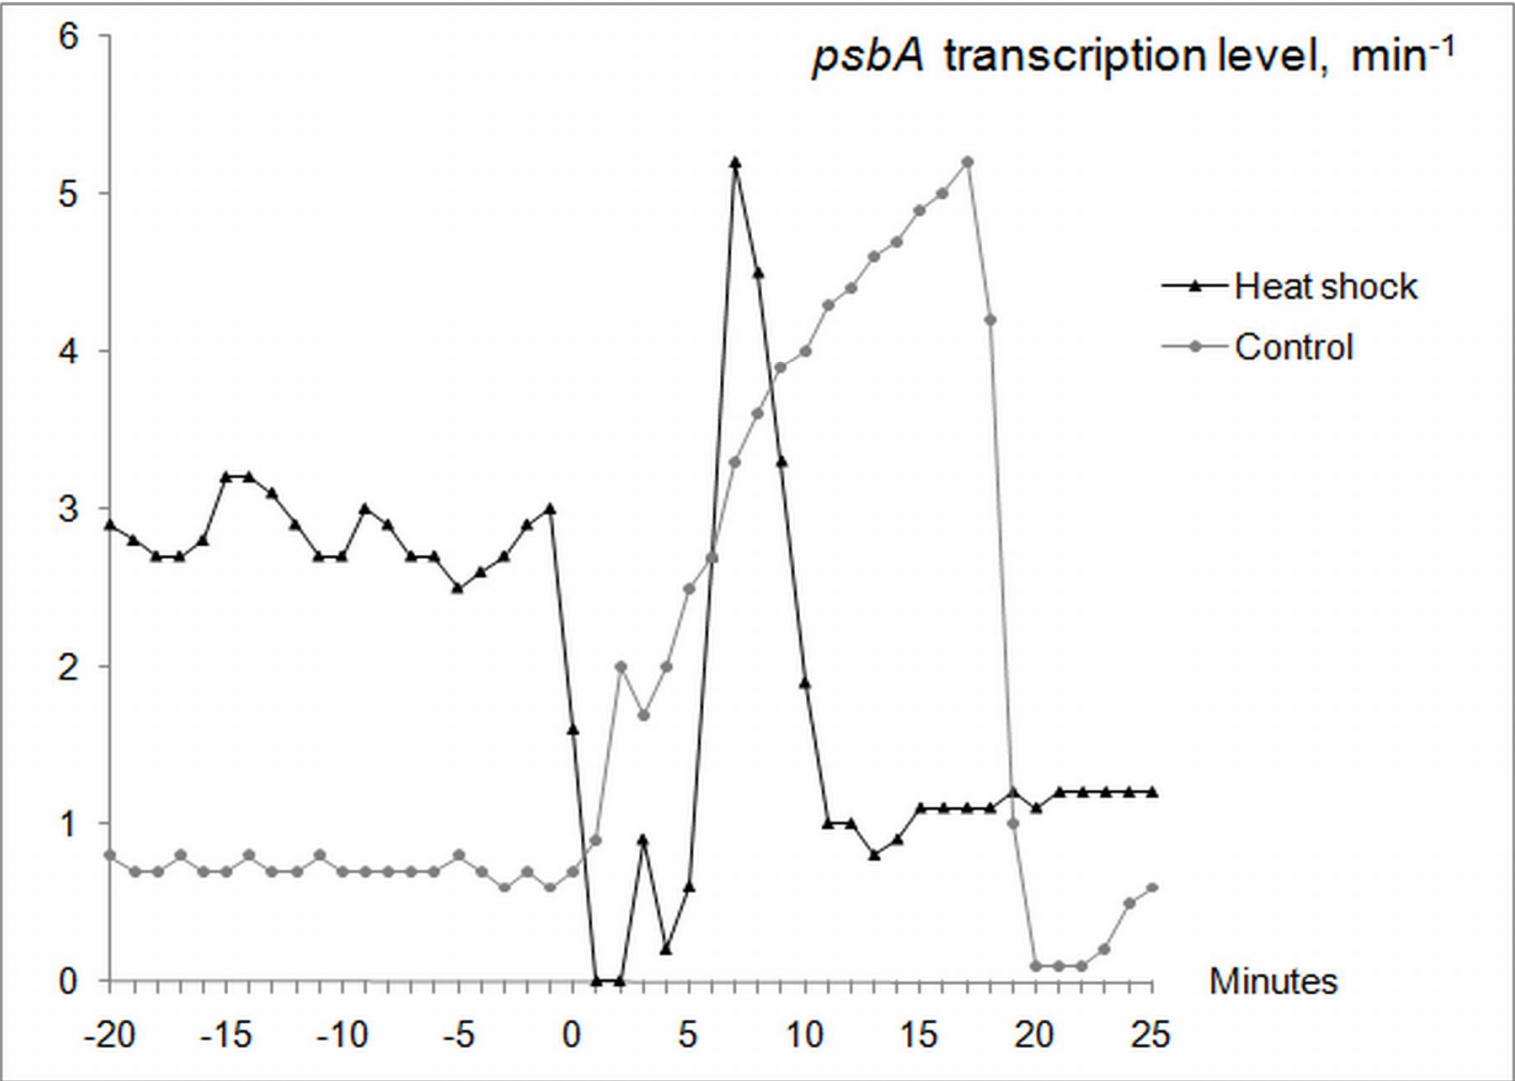

Experimental conditions. The zero on the horizontal axis corresponds to the heat shock termination

Transcription level of genes *rpl23-rpl2* vs. time measured in the experiment. The zero on the horizontal axis corresponds to the heat shock termination

Transcription level of gene *psbA* vs. time measured in the experiment. The zero on the horizontal axis corresponds to the heat shock termination

The *Hordeum vulgare* chloroplast contains two copies of the following set of genes: *rps12–rps7–ndhB–trnL–trnI–rpl23–rpl2–(trnH)–rps19*. One set competes with neighboring gene *psbA*: P0-*rps12-rps7-ndhB-trnL-P1-trnI-rpl23-rpl2-(trnH-P2)-rps19-(psbA-P3)*, and the other set adjoins the next operon on the same strand: P0-*rps12-rps7-ndhB-trnL-P1-trnI-rpl23-rpl2-(trnH-P2)-rps19-rpl22-rps3-rpl16-rpl14-rps8-infA-rpl36-rps11-rpoA*. The transcription level ratios were measured experimentally for these sets at the temperatures of 21°C and 40°C. Our model predictions conform within experimental error with *in vitro* measurements (the table below) for values of the promoter binding efficiency  $P_0=0.2$ ,  $P_1=0.9$ ,  $P_2=0.3$ ,  $P_3=0.1\text{s}^{-1}$ , and the RNA polymerase elongation rates  $R_{21}=9.2$  and  $R_{40}=36.8\text{bp/s}$  at lower and higher temperatures, respectively.

Genes	Experiment 1 ratio	Experiment 2 ratio	Model ratio
<i>rpl23 – rpl2</i>	2.15	2.69	2.37
<i>psbA</i>	0.53	0.55	0.54

## Multiple alignment of the *rps20* promoter regions (rhodophytes, cryptophytes, cyanobacteria):

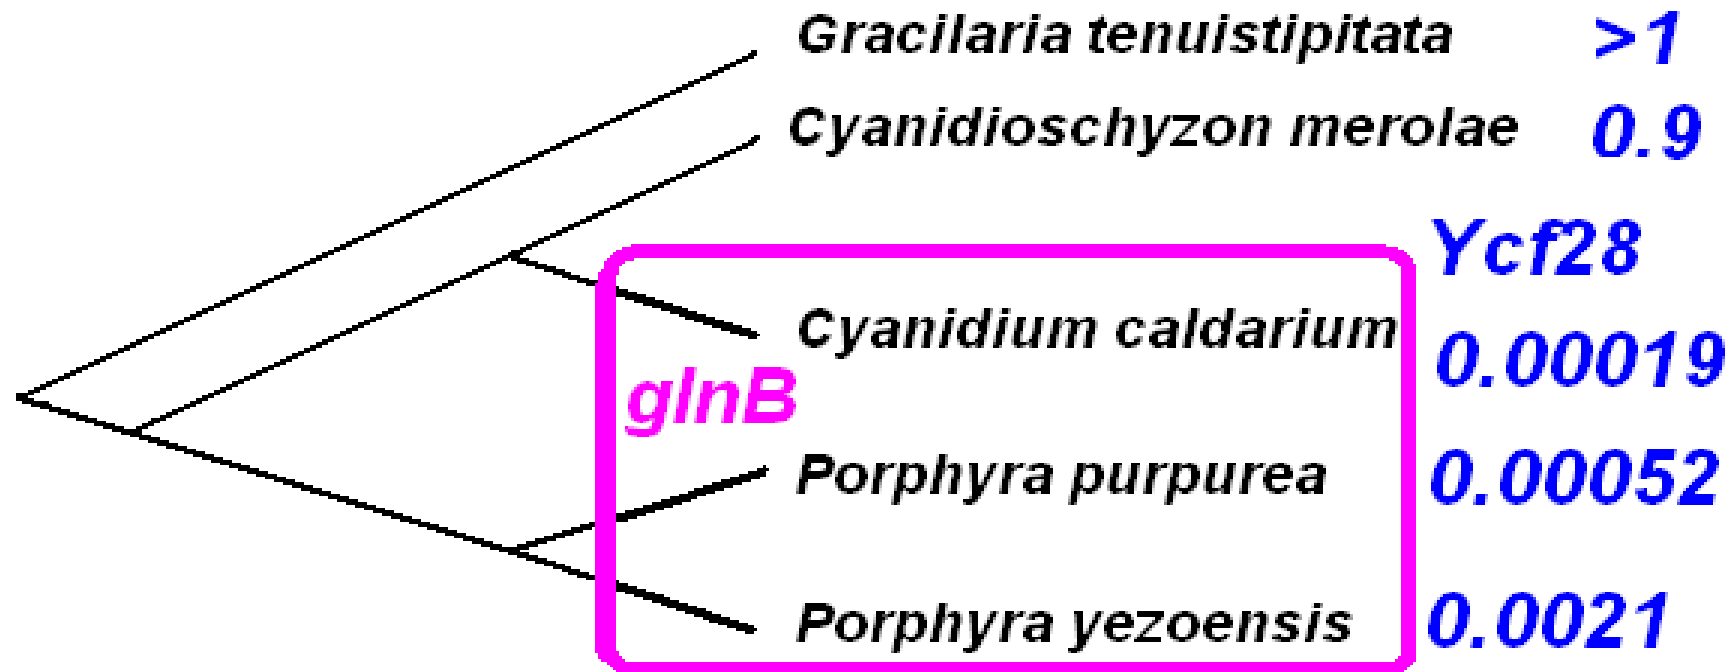

Species	Promoter upstream <i>rps20</i> ( <i>rpsT</i> )
<i>Cyanidioschyzon_merolae</i>	TCTTGCTTTTGGCCATCTGCT=ATTTTATCTTTAT
<i>Cyanidium_caldarium</i>	ATTTGTTTATTTTACTTTAAT=ATGATACAGTAAT
<i>Porphyra_purpurea</i>	TATTGCCTATTCTTTTTTTAAATGTTATAATACG
<i>Porphyra_yezoensis</i>	TATTGCCTATTGTTTTCCTTAAATGTTATAATACG
<i>Gracilaria_tenuistipitata</i>	TCTTGCTATTTTAATGTATTAATGATATAATCCA
<i>Guillardia_theta</i>	AATTTATTCCATTATTCTTATAATGTTATAATCCTT
<i>Rhodomonas_salina</i>	TTCTTATTC=ATAATTTGTTCTATGTTATAATCAC
<i>Synechocystis6803</i>	CATTGTCGT=GGCGTCCCAAACGTTAGAATAAC
	-35box EX -10box

the *rps20* promoter is conserved in cyanobacteria and plastids of red and cryptophyte algae;

a two-boxed site binds repressor Ycf28 (promoter close to the consensus); in 3 out of 8 species; in cyanobacteria Ycf28 activates *glnB* transcription

- 1) when *rps20* is antisense to *glnB* ?,
- 2) under the presence of transcription factor *Ycf28* ?:

GlnB is a factor from the PII family involved in protein-protein interaction. Ycf28 (=NtcA) is a transcription factor in plastids of red algae, i.e. it possesses a **crp-domain**;

e values are the similarity between the cpr-consensus from the Pfam database and Ycf28 domain

the RNA polymerase and ribosome proteins-coding locus; it is conserved among Rhodophyta, **while** *Gracilaria* and *Cyanidioschyzon* do not possess gene *glnB* due to a large chromosome deletion;

we found a repressor binding site near the *rps20* promoter **specifically in** *Porphyra* и *Cyanidium*

## The role of the Ycf28 factor (=NtcA):

in *Porphyra* and *Cyanidium* the binding site overlaps the *rps20-rpoBC1C2* promoter, **Ycf28** silences ***rps20*** transcription and thus enhances the transcription of antisense ***glnB*** by relaxing the polymerase competition.

**Hypothesis:** repression of the *rps20-rpoBC1C2* operon relaxes RNA polymerase competition toward transcription of *glnB* → **transcription activation** of *glnB*.

In cyanobacteria, factor NtcA **activates** the *glnB* transcription through protein-DNA interaction [Muro-Pastor et al, 2003, *Plant Physiol Biochem.*]
