We present a short proof of the excluded grid theorem of Robertson and Seymour, the fact that a graph has no large grid minor if and only if it has small tree-width. We further propose a very simple obstruction to small tree-width inspired by that proof, showing that a graph has small tree-width if and only if it contains no large highly connected set of vertices. © 1999 Academic Press

1. INTRODUCTION

The following theorem of Robertson and Seymour [5] plays a fundamental role in their theory of graph minors:

**Theorem 1.** Given any graph $X$, the graphs without an $X$ minor have bounded tree-width if and only if $X$ is planar.

Since planar grids can have arbitrarily large tree-width (see below), the “only if” direction here is immediate: if $X$ is non-planar then no grid has an $X$ minor, and hence the graphs without an $X$ minor have unbounded tree-width. Conversely, we have to show that forbidding any planar minor bounds the tree-width of a graph. And again, since every planar graph $G$ is the minor of some large enough grid (take a drawing of $G$ with “fat”
vertices and superimpose a drawing of a sufficiently fine grid), it suffices to show the following:

**Theorem 2.** For every integer \( r \) there is an integer \( k \) such that every graph of tree-width at least \( k \) has an \( r \times r \) grid minor.

Proofs of Theorem 2 have been given by Robertson and Seymour [5], by Robertson, Seymour, and Thomas [7], and by Reed [3]. All these proofs are long and technical. Our main purpose in this paper is to offer a short and self-contained new proof of Theorem 2. This will be given in Section 3, which can be read independently of the rest of the paper.

We remark that our proof of Theorem 2 may be combined with [4] and [8] to give the shortest known proof of one of the main corollaries of the Robertson–Seymour graph minor theorem (“Wagner’s conjecture”), the “generalized Kuratowski” result that the graphs embeddable in any fixed surface are characterized by finitely many forbidden minors. A proof of the graph minor theorem itself is sketched in [1, Chapter 12]; among other things, the sketch indicates the role that Theorem 1 plays in that proof.

Our second aim in this paper is to draw attention to another obstruction to small tree-width, implied by (but different from) large grid minors: large “highly connected” sets of vertices. In Section 2 we give a very simple proof that a graph has small tree-width if and only if it contains no such set of vertices. A result with a similar flavour has been obtained by Reed as a spin-off of the theory of “brambles” [3, combine Lemma 3.4 with Theorem 2.11].

Our terminology follows [1]. (A general introduction to tree-decompositions and graph minors may also be found there, as well as in [9].) The vertex sets into which a tree-decomposition decomposes a graph will be called the *parts* of that decomposition. For the notion of tree-width, we just recall that tree-decompositions of width \(< k\) may have parts containing up to \( k \) vertices; thus, trees have tree-width 1. If \( C \) is a subgraph of a graph \( G \), we write \( N(C) \) for its set of *neighbours* in \( G - C \), the set of vertices in \( G - C \) adjacent to a vertex in \( C \). A *separation* of \( G \) is an ordered pair \((A, B)\) of subgraphs of \( G \) such that \( A \cup B = G \) and \( E(A) \cap E(B) = \emptyset \); its *order* is the number \(|A \cap B|\). The \( n \times n \) grid is the graph on \( \{1, \ldots, n\}^2 \) with edge set \( \{(i, j)(i', j'): |i - i'| + |j - j'| = 1\} \). We call a set \( X \subseteq V(G) \) *\( k\)-connected* in \( G \) if \(|X| \geq k\) and for all subsets \( Y, Z \subseteq X \) with \(|Y| = |Z| \leq k\) there are \(|Y|\) disjoint \( Y - Z \) paths in \( G \). (The sets \( Y \) and \( Z \) are not required to be disjoint.) \( X \) is *externally \( k\)-connected* if, in addition, the required paths can be chosen without an inner vertex or edge in \( G[X] \). For example, the vertex set of any \( k\)-connected subgraph of \( G \) is \( k\)-connected in \( G \) (though not necessarily externally), but also any horizontal path of the \( k \times k \) grid is \( k\)-connected in the grid, even externally.
2. HIGHLY CONNECTED SETS

In this section we show that a graph has small tree-width if and only if it has no large highly connected sets of vertices. The proof of the first part of the following proposition uses no more than standard tree-decomposition techniques; we include it for the convenience of those readers new to the subject.

**Proposition 3.** Let \( G \) be a graph and \( k > 0 \) an integer.

(i) If \( G \) has tree-width \( < k \) then \( G \) contains no \((k + 1)\)-connected set of size \( \geq 3k \).

(ii) Conversely, if \( G \) contains no externally \((k + 1)\)-connected set of size \( \geq 3k \) then \( G \) has tree-width \( < 4k \).

**Proof.** (i) Choose a tree-decomposition \( (T, (V_r)_{r \in T}) \) of \( G \) of width \( < k \), without loss of generality so that none of the parts \( V_r \) is contained in another. Then for every edge \( e = rs \) of \( T \), the set \( V_r \cap V_s \) has \( < k \) vertices and separates the sets \( U_r := \bigcup_{t \in r} V_t \) and \( U_s := \bigcup_{t \in s} V_t \) in \( G \); here, \( T_r \) and \( T_s \) denote the components of \( T - e \) containing \( r \) and \( s \), respectively. Any separation \( (A, B) \) of \( G \) with vertex sets \( \{ V(A), V(B) \} = \{ U_r, U_s \} \) (and hence \( V(A \cap B) = V_r \cap V_s \)) is said to correspond to \( e \).

Suppose \( X \) is a \((k + 1)\)-connected set of size \( \geq 3k \) in \( G \). Orient every edge \( e \) of \( T \) towards the component \( T' = T - e \) for which \( |X \cap \bigcup_{r \in T} V_r| \) is greater, breaking ties arbitrarily. Choose a vertex \( t \in T \) so that all the edges \( e_1, ..., e_n \) of \( T \) at \( t \) point towards \( t \). For every \( i = 1, ..., n \) pick a separation \((A_i, B_i)\) corresponding to \( e_i \), with \( V_i \subseteq B_i \). Then \( |V(A_i) \cap X| < k \): otherwise, both \( A_i \) and \( B_i \) would have \( k \) vertices in \( X \), and we could extend \( V(A_i \cap B_i) \cap X \) to \( k \)-subsets \( Y \subseteq V(A_i) \cap X \) and \( Z \subseteq V(B_i) \cap X \) that cannot be linked by \( k \) disjoint paths in \( G \) (since \( |A_i \cap B_i| < k \)).

Now let \( i \leq n \) be minimal such that \( |V(A_i) \cup \cdots \cup A| \cap X| > k \), and put \( A := A_1 \cup \cdots \cup A_i \) and \( B := B_1 \cap \cdots \cap B_i \). By the minimality of \( i \) and since \( |V(A_i) \cap X| < k \), we have \( |V(A) \cap X| < 2k \), so \( |V(B) \cap X| > |X| - 2k \geq k \).

As before, we may extend \( V(A \cap B) \cap X \) to \((k + 1)\)-sets \( Y \subseteq V(A) \cap X \) and \( Z \subseteq V(B) \cap X \). As \( V_i \) separates these sets in \( G \) and \( |V_i| \leq k \), this contradicts our assumption that \( X \) is \((k + 1)\)-connected in \( G \).

(ii) We prove the following more general assertion:

If \( h \geq k \) and \( G \) contains no externally \( k \)-connected set of size \( h \), then \( G \) has tree-width \( < h + k - 1 \).

Let \( U \supseteq V(G) \) be maximal such that \( G[U] \) has a tree-decomposition \( \mathcal{D} \) of width \( < h + k - 1 \) such that every component \( C \) of \( G - U \) has at most \( h \) neighbours in \( U \) and these lie in one part of \( \mathcal{D} \) (depending on \( C \)).
We claim that \( U = V(G) \). Suppose not. Let \( C \) be a component of \( G - U \) and write \( X := N(C) \). By assumption, \(|X| \leq h\). In fact \(|X| = h\), since otherwise for any \( e \in V(C) \) we could add \( X \cup \{ e \} \) to \( \mathcal{G} \) as a new part, contradicting the maximality of \( U \). Hence by assumption, \( X \) is not externally \( k \)-connected in \( G \); let \( Y, Z \subseteq X \) be sets to witness this.

By Menger’s theorem, \( Y \) and \( Z \) are separated in \( H := G[V(C) \cup Y \cup Z] - E(G[Y \cup Z]) \) by a set \( S \) of fewer than \(|Y| = |Z| \leq k\) vertices. Let \( X_Y := (X \setminus Z) \cup S \) and \( X_Z := (X \setminus Y) \cup S \). Clearly, \(|X \cap S| \leq h + k - 1\) and \(|X_Y|, |X_Z| < |X| = h\). Moreover, any component \( C' \subseteq C \) of \( G - (U \cup S) \) has all its neighbours in \( X \cup S \), and hence either in \( X_Y \) or in \( X_Z \); otherwise \( H - S \) would contain a \( Y - Z \) path through \( C' \).

Extending \( U \) to \( U \cup S \) and adding \( X \cup S \) to \( \mathcal{G} \) as a new part, we obtain a contradiction to the maximality of \( U \). (Note that \( S \cap C \neq \emptyset \), since \(|S| < |Y| = |Z| \) and \( Y, Z \subseteq N(C) \).)

It is perhaps interesting to note that Proposition 3(i) is best possible (or nearly so) in various ways, and remains so even if we weaken its assertion by inserting “externally” before “\((k+1)\)-connected.” For example, a complete bipartite graph with vertex sets \( X \) and \( Y \) of sizes \( k - 1 \) and \( n \geq k - 1 \), respectively, has tree-width \(< k\) (with parts \( X \cup \{ y \}, y \in Y \)) and clearly \( Y \) is an externally \((k - 1)\)-connected set whose size is not bounded as a function of \( k \). Only slightly less trivially, consider the complete bipartite graph \( G \) with vertex sets \( X \) and \( Y \) of sizes \( k \geq 5 \) and \( 3k \), respectively. Partition \( Y \) into three sets \( Y_1, Y_2, Y_3 \) of size \( k \), and delete a perfect matching from each of the three bipartite subgraphs \( G[X \cup Y_i] \). The resulting graph again has tree-width \(< k\) (with parts \( X \) and \((X \setminus \{ x \}) \cup \{ y \}\) for all \( y \in Y \), where \( x \) is the unique non-neighbour of \( y \)), and an easy application of Hall’s theorem shows that \( Y \) is externally \( k \)-connected in it.

The above example shows that the value of \( k \) in the premise and the value of \((k + 1)\) in the conclusion of Proposition 3(i) are best possible. The value of \( 3k \) in the conclusion is also essentially best possible. This is exemplified by the following graph \( G \) of tree-width \(< k\) that contains an externally \((k + 1)\)-connected (even \(|X|\)-connected) set \( X \) of size \( 3(k - 1) \). First we define a partially ordered set, as follows. Starting with a linearly ordered \((k - 1)\)-set \( R \), we put three linearly ordered \((k - 1)\)-sets \( S_1, S_2, S_3 \) above \( R \), letting elements from different \( S_i \) be incomparable. To make this into a graph, we add all possible edges on \( R \) and join every vertex from one of the \( S_i \) to all the vertices in the \((k - 1)\)-chain directly below it. (Note that this graph has a tree-decomposition into its \( k \)-cliques.) Finally, we add new independent \((k - 1)\)-sets \( X_1, X_2, X_3 \), joining \( X_i \) completely to \( S_i \) for each \( i = 1, 2, 3 \). It is now easily checked that any two (disjoint) sets \( Y, Z \subseteq X_1 \cup X_2 \cup X_3 \) of equal size can be linked in \( G \) by \(|Y| = |Z|\) disjoint paths: vertices \( y, z \) in the same \( X_i \) can be linked via the corresponding \( S_i \), using...
its highest vertices, and any remaining pairs $y, z$ can be joined via the lower vertices of the $S_i$ and $R$.

Proposition 3(ii) is also best possible: the complete graph on $4k$ vertices shows that we cannot strengthen the conclusion, while the complete graph on $4k + 1$ vertices shows that we cannot weaken the premise in either way. Similarly, $K_{k+k-1}$ and $K_{k+k}$ (for $h \geq 2k + 2$) show that the more general assertion we prove is best possible.

3. GRID MINORS

We now present our proof of Theorem 2. Very roughly, we shall assume that a given graph $G$ has large tree-width, find a large highly connected set $X$ in $G$ as in Proposition 3(ii), and use its connecting paths $P$ to form a grid. Of course, this will be possible only if those paths intersect sufficiently. If they do not, we shall try instead to partition $X$ into many sets that can be linked pairwise by mutually disjoint paths, so that contracting these sets will give us a subdivision of a large complete graph. Since we may only contract connected sets when forming a minor, our first task will thus be to strengthen Proposition 3(ii) so as to give $X$ a partition into many sets that can be made connected in a part of $G$ not used by the paths $P$.

In order to make this section self-contained, we prove all the lemmas that we need from first principles. This goes in particular for our first lemma, the strengthening of Proposition 3(ii) indicated above.

Let us call a separation $(A, B)$ a premesh if all the edges of $A \cap B$ lie in $A$ and $A$ contains a tree $T$ with the following properties:

- $T$ has maximum degree $\leq 3$;
- every vertex of $A \cap B$ lies in $T$ and has degree $\leq 2$ in $T$;
- $T$ has a leaf in $A \cap B$ (that is, a vertex of degree $\leq 1$).

A premesh $(A, B)$ will be called a $k$-mesh if $V(A \cap B)$ is externally $k$-connected in $B$, and the graph $G = A \cup B$ is said to have this premesh or $k$-mesh.

**Lemma 4.** Let $G$ be a graph and let $h \geq k \geq 1$ be integers. If $G$ has no $k$-mesh of order $h$ then $G$ has tree-width $< h + k - 1$.

**Proof.** We may assume that $G$ is connected. Let $U \subseteq V(G)$ be maximal such that $G[U]$ has a tree-decomposition $\mathcal{D}$ of width $< h + k - 1$, with the additional property that, for every component $C$ of $G - U$, the neighbours of $C$ in $U$ lie in one part of $\mathcal{D}$ and $(G - C, C)$ is a premesh of order $\leq h$, where $C := G[V(C) \cup N(C)] - E(G[N(C)])$. Clearly, $U \neq \emptyset$. 
We claim that $U = V(G)$. Suppose not. Let $C$ be a component of $G - U$, put $X := N(C)$, and let $T$ be a tree associated with the premesh $(G - C, C)$.

By assumption, $|X| \leq h$; let us show that equality holds here. If not, let $u \in X$ be a leaf of $T$ and $v$ a neighbour of $u$ in $C$. Put $U' := U \cup \{v\}$ and $X' := X \cup \{v\}$, let $T'$ be the tree obtained from $T$ by joining $v$ to $u$, and let $\mathcal{D}'$ be the tree-decomposition of $G[U']$ obtained from $\mathcal{D}$ by adding $X'$ as a new part. Clearly $\mathcal{D}'$ still has width $\leq h + k - 1$. Consider a component $C'$ of $G - U'$. If $C' \cap C = \emptyset$ then $C'$ is also a component of $G - U$, so $N(C')$ lies inside a part of $\mathcal{D}$ (and hence of $\mathcal{D}'$), and $(G - C', \bar{C})$ is a premesh of order $|X| - |Y| + |S| = h - |Y| + k' < h$, contradictory to the maximality of $U$.

Thus $|X| = h$, so by assumption our premesh $(G - C, \bar{C})$ cannot be a $k$-mesh. Hence by Menger's theorem, there are sets $Y, Z \subseteq X$ of equal size $\leq k$ that are separated in $H := C[V(C) \cup Y \cup Z]$ by a set $S$ of $k' < |Y| = |Z|$ vertices, one from each of a family $(P_s)_{s \in S}$ of disjoint $Y - Z$ paths in $H$.

Put $X' := X \cup S$ and $U' := U \cup S$, and let $\mathcal{D}'$ be the tree-decomposition of $G[U']$ obtained from $\mathcal{D}$ by adding $X'$ as a new part. Clearly, $|X'| \leq |X| + |S| \leq h + k - 1$. We show that $U'$ contradicts the maximality of $U$.

Since $Y \cup Z \subseteq N(C)$ and $|S| < |Y| = |Z|$ we have $S \cap C \neq \emptyset$, so $U'$ is larger than $U$. Let $C'$ be a component of $G - U'$. If $C' \cap C = \emptyset$, we argue as earlier. So $C' \subseteq C$ and $N(C') \subseteq X'$. As before, at least one neighbour $v$ of $C'$ lies in $S \cap C$. By definition of $S$, $C'$ cannot have neighbours in both $Y \setminus S$ and $Z \setminus S$; we assume it has none in $Y \setminus S$. Let $T''$ be the union of $T$ and all the $Y - S$ subpaths of paths $P_s$ with $s \in N(C') \cap C$; since these subpaths start in $Y \setminus S$ and have no inner vertices in $X'$, they cannot meet $C'$. Therefore $(G - C', \bar{C})$ is a premesh with tree $T''$ and leaf $v$; the degree conditions on $T'$ are easily checked. Its order is $|N(C')| \leq |X| - |Y| + |S| = h - |Y| + k' < h$, a contradiction to the maximality of $U$.

**Lemma 5.** Let $k \geq 2$ be an integer. Let $T$ be a tree of maximum degree $\leq 3$ and $X \subseteq V(T)$. Then $T$ has a set $E$ of edges such that every component of $T - E$ has between $k$ and $2k - 2$ vertices in $X$, except that one such component may have fewer vertices in $X$.

**Proof.** Induction on $|X|$. If $|X| \leq 2k - 2$ we put $E = \emptyset$. So assume that $|X| \geq 2k - 1$. Let $e$ be an edge of $T$ such that some component $T'$ of $T - e$ has at least $k$ vertices in $X$ and $T'$ is as small as possible. As $A(T) \leq 3$, the end of $e$ in $T'$ has degree at most two in $T'$, so the minimality of $T'$ implies that $|X \cap V(T')| \leq 2k - 2$. We finish by applying the induction hypothesis to $T - T'$. □
Lemma 6. Let $G$ be a bipartite graph with bipartition $(A, B)$, $|A| = a$, $|B| = b$, and let $c \leq a$ and $d \leq b$ be positive integers. Assume that $G$ has at most $(a-c)(b-d)/d$ edges. Then there exist $C \subseteq A$ and $D \subseteq B$ such that $|C| = c$ and $|D| = d$ and $C \cup D$ is independent in $G$.

Proof. As $|G| \leq (a-c)(b-d)/d$, fewer than $b-d$ vertices in $B$ have more than $(a-c)/d$ neighbours in $A$. Choose $D \subseteq B$ so that $|D| = d$ and each vertex in $D$ has at most $(a-c)/d$ neighbours in $A$. Then $D$ sends a total of at most $a-c$ edges to $A$, so $A$ has a subset $C$ of $c$ vertices without a neighbour in $D$.

Given a tree $T$, call an $r$-tuple $(x_1, \ldots, x_r)$ of distinct vertices of $T$ good if, for every $j = 1, \ldots, r-1$, the $x_j - x_{j+1}$ path in $T$ contains none of the other vertices in this $r$-tuple.

Lemma 7. Every tree of order $\geq r(r-1)$ has a good $r$-tuple of vertices.

Proof. If $x$ is any vertex of a tree $T$, then $T$ is the union of its subpaths $x \cdots y$, where $y$ ranges over its leaves. Hence unless one of these paths has at least $r$ vertices, $T$ has at least $|T|/(r-1)$ leaves. Since any path of $r$ vertices and any set of $r$ leaves defines a good $r$-tuple in $T$, this proves the assertion.

Our next lemma shows how to obtain a grid from two large systems of paths that intersect in a particularly orderly way.

Lemma 8. Let $d, r \geq 2$ be integers such that $d \geq r^{2r+2}$. Let $G$ be a graph containing a set $H$ of $r^2-1$ disjoint paths and a set $V = \{V_1, \ldots, V_d\}$ of $d$ disjoint paths. Assume that every path in $H$ meets every path in $V$, and that each path $H \in H$ consists of $d$ consecutive (vertex disjoint) segments such that $V_i$ meets $H$ only in its $i$th segment, for every $i = 1, \ldots, d$. Then $G$ has an $r \times r$ grid minor.

Proof. For each $i = 1, \ldots, d$, consider the graph with vertex set $H$ in which two paths are adjacent whenever $V_i$ contains a subpath between them that meets no other path in $H$. Since $V_i$ meets every path in $H$, this is a connected graph; let $T_i$ be a spanning tree in it. Since $|H| \geq r(r-1)$, Lemma 7 implies that each of these $d \geq r^2(r^2)^{r^2}$ trees $T_i$ has a good $r$-tuple of vertices. Since there are no more than $(r^2)^{r^2}$ distinct $r$-tuples on $H$, some $r^2$ of the trees $T_i$ have a common good $r$-tuple $(H', \ldots, H')$. Let $I = \{i_1, \ldots, i_{r^2}\}$ be the index set of these trees (with $i_j < i_k$ for $j < k$) and put $H^* := \{H', \ldots, H'\}$.

Here is an informal description of how we construct our $r \times r$ grid. Its “horizontal” paths will be the paths $H', \ldots, H'$. Its “vertical” paths will be pieced together edge by edge, as follows. The $r-1$ edges of the first vertical
path will come from the first \( r - 1 \) trees \( T_i \), trees with their index \( i \) among the first \( r \) elements of \( I \). More precisely, its “edge” between \( H^j \) and \( H^j+1 \) will be the sequence of subpaths of \( V_j \) (together with some connecting horizontal bits taken from paths in \( \mathcal{M} \setminus \mathcal{M}' \)) induced by the edges of an \( H^j - H^j+1 \) path in \( T_0 \) that has no inner vertices in \( \mathcal{M}' \). (This is why we need \( (H^j, \ldots, H^r) \) to be a good \( r \)-tuple in every tree \( T_i \).) Similarly, the \( j \)th edge of the second vertical path will come from an \( H^j - H^j+1 \) path in \( T_{j+1} \), and so on. To merge these individual edges into \( r \) vertical paths, we then contract in each \( H^j \) the initial segment that meets the first \( r \) paths \( V_i \) with \( i \in I \), then contract the segment that meets the following \( r \) paths \( V_i \) with \( i \in I \), and so on.

Formally, we proceed as follows. For all \( j, k \in \{1, \ldots, r\} \), consider the minimal subpath \( H_i^j \) of \( H^j \) that contains the \( i \)th segment of \( H^j \) for all \( i \) with \( t - 1 < i \leq t_0 \) (put \( t_0 := 0 \)). Let \( H^j \) be obtained from \( H^j \) by first deleting any vertices following its \( t+1 \)th segment and then contracting every subpath \( H_i^j \) to one vertex \( v_i^j \). Thus, \( H^j = v_{1}^{t} \).

Given \( j \in \{1, \ldots, r - 1\} \) and \( k \in \{1, \ldots, r\} \), we have to define a path \( V_i^j \) that will form the subdivided “vertical edge” \( v_i^j v_k^{j+1} \). This path will consist of segments of the path \( V_i \) together with some otherwise unused segments of paths from \( \mathcal{M} \setminus \mathcal{M}' \), for \( i := t_{k-1} + r + j \); recall that, by definition of \( \mathcal{M} \) and \( \mathcal{M}' \), this \( V_i \) does indeed meet \( H^j \) and \( H^j+1 \), this \( V_i \) does indeed meet \( H^j \) and \( H^j+1 \) precisely in vertices that were contracted into \( v_i^j \) and \( v_k^{j+1} \), respectively. To define \( V_i^j \), consider an \( H^j - H^j+1 \) path \( P = H_i^{j} \cdots H_i^{j+1} \) in \( T_i \) that has no inner vertices in \( \mathcal{M}' \). Every edge \( H_i^{j} H_i^{j+1} \) of \( P \) corresponds to an \( H_i - H_i+1 \) subpath of \( V_i \) that has no inner vertex on any path in \( \mathcal{M} \). Together with (parts of) the \( j \)th segments of \( H_2, \ldots, H_{j-1} \), these subpaths of \( V_i \) form an \( H^j - H^j+1 \) path \( P \) that has no inner vertices on any of the paths \( H^j, \ldots, H^r \) and meets no path from \( \mathcal{M} \) outside its \( j \)th segment. Replacing the ends of \( P \) on \( H^j \) and \( H^j+1 \) with \( v_i^j \) and \( v_k^{j+1} \), respectively, we obtain our desired path \( V_i^j \) forming the \( j \)th (subdivided) edge of the \( j \)th “vertical” path of our grid. Since the paths \( P \) are disjoint for different \( i \) and different pairs \((j, k)\) do give rise to different \( i \), the paths \( V_i^j \) are disjoint except for possible common ends \( v_i^j \). Moreover, they have no inner vertices on any of the paths \( H^j, \ldots, H^r \); because none of these \( H^j \) is an inner vertex of any of the paths \( P \subseteq T_i \) used in the construction of \( V_i^j \).

We are now ready to prove the following quantitative version of Theorem 2.

**Theorem 9.** Let \( r, m > 0 \) be integers, and let \( G \) be a graph of tree-width at least \( r \log (r+2) \). Then \( G \) contains either \( K_m \) or the \( r \times r \) grid as a minor.

**Proof.** Since \( K_m \) contains the \( r \times r \) grid as a subgraph, we may assume that \( 2 \leq m \leq r^2 \). Put \( c := r^2 \) and \( k := e^{c / 2} \). Then \( 2m + 2 \leq c \), so \( G \) has
tree-width at least \( w^2 \geq 2m+2 \): more than enough for Lemma 4 to ensure that \( G \) contains a \( k \)-mesh \((A, B)\) of order \((2m+1)(k-1)\). Let \( T \subseteq A \) be a tree associated with the premesh \((A, B)\); thus, \( X := V(A \cap B) \subseteq V(T) \). By Lemma 5, \( T \) has \((|X|-(k-1))(2k-2) = m \) disjoint subtrees each containing at least \( k \) vertices of \( X \); let \( A_1, \ldots, A_m \) be the vertex sets of these trees. By definition of a \( k \)-mesh, \( B \) contains for all \( 1 \leq i < j \leq m \) a set \( \mathcal{P}_i \) of \( k \) disjoint \( A_i - A_j \) paths that have no inner vertices in \( A \). These sets \( \mathcal{P}_i \) will shrink a little and be otherwise modified later in the proof, but they will always consist of "many" disjoint \( A_i - A_j \) paths.

One option in our proof will be to find single paths \( P_{ij} \in \mathcal{P}_i \) that are disjoint for different pairs \( ij \) and thus link up the sets \( A_i \) to form a \( K_m \) minor of \( G \). If this fails, we shall instead exhibit two specific sets \( \mathcal{P}_i \) and \( \mathcal{P}_{pq} \) such that many paths of \( \mathcal{P}_i \) meet many paths of \( \mathcal{P}_{pq} \), forming an \( r \times r \) grid between them by Lemma 8.

Let us impose a linear ordering on the index pairs \( ij \) by fixing an arbitrary bijection \( \sigma: \{ij \mid 1 \leq i < j \leq m\} \rightarrow \{0, 1, \ldots, \binom{m}{2}-1\} \). For \( \ell = 0, 1, \ldots \) in turn, we shall consider the pair \( pq \) with \( \sigma(pq) = \ell \) and choose an \( A_p - A_q \) path \( P_{pq} \) that is disjoint from all previously selected such paths, i.e., from the paths \( P_{st} \) with \( \sigma(st) < \ell \). At the same time, we shall replace all the "later" sets \( \mathcal{P}_i --- or what has become of them--- by smaller sets containing only paths that are disjoint from \( P_{pq} \). Thus for each pair \( ij \), we shall define a sequence \( \mathcal{P}_i = \mathcal{P}_{i0}, \mathcal{P}_{i1}, \ldots \) of smaller and smaller sets of paths, which eventually collapses to \( \mathcal{P}_i = \{P_{ij}\} \) when \( \ell \) has risen to \( \ell = \sigma(ij) \).

More formally, let \( \ell^* \leq \binom{m}{2} \) be maximal such that, for all \( 0 \leq \ell < \ell^* \) and all \( 1 \leq i < j \leq m \), there exist sets \( \mathcal{P}_i^\ell \) satisfying the following five conditions:

(i) \( \mathcal{P}_i^\ell \) is a non-empty set of disjoint \( A_i - A_j \) paths in \( B \) that meet \( A \) only in their endpoints.

As soon as a set \( \mathcal{P}_i^\ell \) is defined, we shall write \( H_i^\ell := \bigcup \mathcal{P}_i^\ell \) for the union of its paths.

(ii) If \( \sigma(ij) < \ell \) then \( \mathcal{P}_i^\ell \) has exactly one element \( P_{ij} \), and \( P_{ij} \) does not meet any path belonging to a set \( \mathcal{P}_i^{\ell'} \) with \( i \neq st \).

(iii) If \( \sigma(ij) = \ell \), then \(|\mathcal{P}_i^\ell| = k/c^{2\ell}\).

(iv) If \( \sigma(ij) > \ell \), then \(|\mathcal{P}_i^\ell| = k/c^{2\ell+1}\).

(v) If \( \ell = \sigma(pq) \leq \sigma(ij) \), then for every \( e \in E(H^\ell_i) \cap E(H^\ell_{pq}) \) there are no \( k/c^{2\ell+1} \) disjoint paths from \( A_i \) to \( A_j \) in the graph \( (H^\ell_{pq} \cup H^\ell_i) - e \).

Note that, since \( \sigma(ij) < \binom{m}{2} \) by definition of \( \sigma \), conditions (iii) and (iv) imply that \(|\mathcal{P}_i^\ell| \geq c^\ell\) whenever \( \sigma(ij) \geq \ell \).

Clearly if \( \ell^* = \binom{m}{2} \), then by (i) and (ii) we have a (subdivided) \( K_m \) minor with branch sets \( A_1, \ldots, A_m \) in \( G \). Suppose then that \( \ell^* < \binom{m}{2} \). Let us show that \( \ell^* > 0 \). Let \( pq := \sigma^{-1}(0) \) and put \( \mathcal{P}_{pq} := \mathcal{P}_{pq} \). To define \( \mathcal{P}_q^\ell \) for \( \sigma(ij) > 0 \)
put \( H_\ell := \bigcup \mathcal{P}_\ell \) and let \( F \subseteq E(H_\ell) \setminus E(H_{\ell+1}^0) \) be maximal such that 

\[(H_{\ell+1}^0 \cup H_\ell) - F \text{ still contains } k/c \text{ disjoint paths from } A_i \text{ to } A_j; \]

then let \( \mathcal{P}_\ell \) be such a set of paths. As any vertex of \( A \) on these paths lies in \( A_i \cup A_j \) (by definition of \( H_{\ell+1}^0 \) and \( H_\ell \)), we may assume that they have no inner vertices in \( A \). Thus our choice of \( \mathcal{P}_\ell \) satisfies (i)-(v).

Having shown that \( \ell^* > 0 \), let us now consider \( \ell := \ell^* - 1 \). Thus, conditions (i)-(v) are satisfied for \( \ell \) but cannot be satisfied for \( \ell + 1 \). Let \( pq := \sigma^{-1}(\ell) \). If \( \mathcal{P}_\ell \) contains a path \( P \) that avoids a set \( \mathcal{Q}_\ell \) of some \( |\mathcal{P}_\ell|/c \) of the paths in \( \mathcal{P}_\ell \) for all \( ij \) with \( \sigma(ij) > \ell \), then we can define \( \mathcal{P}_\ell^{\ell+1} \) for all \( ij \) as before (with a contradiction). Indeed, let \( st := \sigma^{-1}(\ell + 1) \) and put \( \mathcal{P}_\ell^{\ell+1} := \mathcal{P}_\ell \). For \( \sigma(ij) > \ell + 1 \) write \( H_\ell := \bigcup \mathcal{Q}_\ell \), let \( F \subseteq E(H_\ell) \setminus E(H_{\ell+1}^0) \) be maximal such that \( (H_{\ell+1}^0 \cup H_\ell) - F \) still contains at least \( |\mathcal{P}_\ell|/c^2 \) disjoint paths from \( A_i \) to \( A_j \) and let \( \mathcal{P}_\ell^{\ell+1} \) be such a set of paths. Setting \( \mathcal{P}_\ell^{\ell+1} := \{ P \} \) and \( \mathcal{P}_\ell^{\ell+1} := \{ P_\ell^{\ell+1} \} \) for \( \sigma(ij) < \ell \) then gives us a family of sets \( \mathcal{P}_\ell^{\ell+1} \) that contradicts the maximality of \( \ell^* \).

Thus for every path \( P \in \mathcal{P}_\ell \) there exists a pair \( ij \) with \( \sigma(ij) > \ell \) such that \( P \) avoids fewer than \( |\mathcal{P}_\ell|/c \) of the paths in \( \mathcal{P}_\ell \). For some \( \ell \) of the paths in \( \mathcal{P}_\ell \) of these \( P \) that pair \( ij \) will be the same; let \( \mathcal{P} \) denote the set of those \( P \), and keep \( ij \) fixed from now on. Note that \( |\mathcal{P}| \geq \frac{|\mathcal{P}_\ell|}{\sqrt{c}} = c \frac{|\mathcal{P}_\ell^{\ell+1}|}{\sqrt{c}} \) by (iii) and (iv).

Let us use Lemma 6 to find sets \( \mathcal{P} \subseteq \mathcal{P}_\ell \) and \( \mathcal{X} \subseteq \mathcal{P}_\ell \) such that

\[ |\mathcal{P}| \geq \frac{1}{2}|\mathcal{P}| \quad \left( \geq \frac{c}{m^2}|\mathcal{P}_\ell| \right) \]

and every path in \( \mathcal{P} \) meets every path in \( \mathcal{X} \). We have to check that the bipartite graph with vertex sets \( \mathcal{P} \) and \( \mathcal{P}_\ell \) in which \( P \in \mathcal{P} \) is adjacent to \( Q \in \mathcal{P}_\ell \) whenever \( P \cap Q = \emptyset \) does not have too many edges. Since every \( P \in \mathcal{P} \) has fewer than \( |\mathcal{P}_\ell|/c \) neighbours (by definition of \( \mathcal{P} \)), this graph has indeed at most

\[ |\mathcal{P}| \frac{|\mathcal{P}_\ell|}{c} \leq \frac{|\mathcal{P}|}{2} |\mathcal{P}_\ell|/2^2 \]

\[ \leq \frac{|\mathcal{P}|}{2} (\frac{|\mathcal{P}_\ell|}{|\mathcal{P}_\ell^{\ell+1}|} - 1) \]

\[ = (|\mathcal{P}| - |\mathcal{P}|/2^2) (\frac{|\mathcal{P}_\ell|}{|\mathcal{P}_\ell^{\ell+1}|} - 1) \]

edges, as required. Hence, \( \mathcal{P} \) and \( \mathcal{X} \) exist as claimed.

Pick a path \( Q \in \mathcal{X} \), and put

\[ d := \frac{1}{\sqrt{c}} m = \varepsilon^{2r-4}/m \geq r^{2r+2}. \]
HIGHLY CONNECTED SETS AND TANGLES

For \( n = 1, 2, \ldots, d - 1 \) let \( e_n \) be the first edge of \( Q \) (on its way from \( A_i \) to \( A_j \)) such that the initial component \( Q_n \) of \( Q - e_n \) meets at least \( nd |P'_d| \) different paths from \( r' \), and thus that \( e_n \) is not an edge of \( H'_d \). As any two vertices of \( Q \) that lie on different paths from \( r' \) are separated in \( Q \) by an edge not in \( H'_d \), each of these \( Q_n \) meets exactly \( nd |P'_d| \) paths from \( r' \). Put \( Q_0 := \emptyset \) and \( Q_d := Q \). Since \( |r'| \geq d^2 |P'_d| \), we have thus divided \( Q \) into \( d \) consecutive disjoint segments \( Q'_n := Q_n - Q_{n-1} \) each meeting at least \( d |P'_d| \) paths from \( r' \).

For each \( n = 1, \ldots, d - 1 \), Menger’s theorem and conditions (iv) and (v) imply that \( H'_d \cup \overline{H}'_d \) has a set \( S_n \) of \( |P'_d| - 1 \) vertices such that \( (H'_d \cup \overline{H}'_d) - e_n - S_n \) contains no path from \( A_i \) to \( A_j \). Let \( S \) denote the union of all these sets \( S_n \). Then \( |S| < d |P'_d| \), so each \( Q'_n \) meets at least one path \( V_n \in r' \) that avoids \( S \).

Clearly, each \( S_n \) consists of a choice of exactly one vertex \( x \) from every path \( P \in P'_d \setminus \{Q\} \). Denote the initial component of \( P - x \) by \( P_n \), put \( P_0 := \emptyset \) and \( P_d := P \), and let \( P'_n := P_n - P_{n-1} \) for \( n = 1, \ldots, d \). The separation properties of the sets \( S_n \) now imply that \( V_n \cap P \subseteq P_n \) for \( n = 1, \ldots, d \) (and hence in particular, that \( P'_n \neq \emptyset \), i.e., that \( P_{n-1} \subseteq P_n \)). Indeed \( V_n \) cannot meet \( P_{n-1} \), because \( P_{n-1} \cup V_n \cup (Q - Q_{n-1}) \) would then contain an \( A_i - A_j \) path in \( (H'_d \cup \overline{H}'_d) - e_n - S_{n-1} \), and likewise (consider \( S_n \) \( V_n \) cannot meet \( P - P_n \). Thus for all \( n = 1, \ldots, d \), the path \( V_n \) meets every path \( P \in \mathcal{P} \setminus \{Q\} \) precisely in its \( n \)th segment \( P_n \). Applying Lemma 8 to the path systems \( \mathcal{P} \setminus \{Q\} \) and \( \{V_1, \ldots, V_d\} \) now yields the desired grid minor.

To conclude, let us remark that our upper bound of \( r^4m(r+2) \leq 2^{5r^2 \log r} \) for the tree-width of a graph without an \( r \times r \) grid minor is most likely far from best possible. Robertson, Seymour and Thomas [7] obtain an only slightly better bound of about \( 2^{nr} \), but they suspect that the correct order might be as low as \( r^2 \log r \).

4. HIGHLY CONNECTED SETS AND TANGLES

The proofs of Theorem 2 given in [7] and [3] rely heavily on a concept central to the Robertson-Seymour theory of minors but not so far considered in this paper, the concept of a tangle introduced in [6]. Both these proofs build on the fact that, if the tree-width of a graph is large, then the graph contains a large tangle, and use the tangle for the construction of a grid minor.

While it is easy to see that graphs with a large tangle must have large tree-width—the proof is similar to our proof of Proposition 3(i), see [6] or [3]—its converse, the direction needed for the proof of Theorem 2 in [7]
and [3], is not immediate. However, this direction follows easily from our Proposition 3(ii), and the purpose of this section is to show how.

Let \( k \geq 1 \) be an integer. A \textit{tangle of order} \( k \) in a graph \( G \) is a set \( \mathcal{T} \) of separations of \( G \), each of order \(< k \), that satisfies the following conditions (cf. [6]):

\begin{enumerate}
  \item[(T1)] if \((A,B)\) is any separation of \( G \) of order \(< k \), then either \((A,B) \in \mathcal{T}\) or \((B,A) \in \mathcal{T}\);
  \item[(T2)] if \((A_1, B_1), (A_2, B_2), (A_3, B_3) \in \mathcal{T}\), then \( A_1 \cup A_2 \cup A_3 \neq G \);
  \item[(T3)] if \((A, B) \in \mathcal{T}\), then \( V(A) \neq V(G) \).
\end{enumerate}

As shown in [6, (5.2)], any graph with a tangle of order \( k \) has tree-width at least \( k - 1 \), and any graph of tree-width at least \( k - 1 \) has a tangle of order at least \( \frac{3}{2}k \). Reed [3] gives a simple proof that graphs of tree-width \( \geq 3(k - 1) \) have a tangle of order \( k \); his proof, however, builds on a non-trivial duality theorem for tree-width due to Seymour and Thomas. Trading just a little more quantitative exactness for simplicity of proof, we observe the following corollary to Proposition 3:

\textbf{Proposition 10.} Any graph of tree-width at least \( 4k \) has a tangle of order \( k \).

\textbf{Proof.} If a graph \( G \) has tree-width \( \geq 4k \) then, by Proposition 3(ii), \( G \) contains a \( k \)-connected set \( X \) of size \( 3k \). Let \( \mathcal{T} \) be the set of all separations \((A,B)\) of order \(< k \) in \( G \) such that \( |V(A) \cap X| \leq |V(B) \cap X| \). Then \( |V(A) \cap X| < k \) for all \((A,B) \in \mathcal{T}\) (since \( X \) is \( k \)-connected in \( G \) but \( |A \cap B| < k \)), implying (T2) and (T3). Hence \( \mathcal{T} \) is a tangle of order \( k \). \( \blacksquare \)
